

In one embodiment, the nucleotide and polypeptide sequences of the present invention may be used to design selective CA inhibitors. Studies have also shown that the different alpha-CA have different inhibitor binding properties (Sly et al., (1995), supra), suggesting that it may be possible to provide compounds that inhibit a CA isozyme of interest, such as CA II, while not binding to or inhibiting related enzymes such as the polypeptide of SEQ ID No. 390. The nucleic acid and polypeptide sequences of the invention can be used in computer based drug design or for carrying out binding predictions with candidate CA inhibitors in view of the extensive structural information publicly available for CA enzymes. In preferred embodiments, the nucleic acid and polypeptide of the invention is used in drug screening assays, including both cell based and non cell based assays.

10 In one embodiment, a nucleotide or polypeptide sequence of the invention is brought into contact with a candidate CA inhibitor (such as a CA II inhibitor), and binding of the candidate inhibitor to the polypeptide of the invention, or the activity of the polypeptide of the invention is detected. Activity of the polypeptide of the invention may be CA activity, or any other suitable activity possessed by the polypeptide of the invention which may be inhibited by binding of the candidate

15 substance. In preferred embodiments, a panel of CA isozymes including the polypeptide of the invention are screened against the candidate substance, including the polypeptide of SEQ ID No 39 and one or more enzymes selected from the group consisting of CA I, CA III, CA IV, CA VI, a CARP including but not limited to CARP VII, CARP X, CARP XI. In preferred embodiments, a candidate CA inhibitor is screened against one or more non-catalytic CA related proteins to

20 eliminate undesired inhibition of these enzymes which may be involved in other important physiological functions. Means to conduct such drug screening assays are well known in the art.

Increasing alpha-CA activity for the treatment of alpha-CA deficiency disease

The polypeptide of the invention may also be used as a source of CA activity, such as for the treatment of disease. The defects in carbonic anhydrases are the cause of several diseases,

25 including osteopetrosis (abnormally dense bone) renal tubular acidosis, cerebral calcification and mental retardation. Also, a carbonic anhydrase-related protein is described as being linked to cone-rod retinal dystrophy (Bellinghan et al., 1998, Biochem. Biophys. Res. Comm.: 253, 364-367).

In one aspect, the invention thus involves increasing CA activity by providing increased activity of the polypeptide of SEQ ID No. 390. Increased activity of the polypeptide of SEQ ID No

30 390 can be provided by any suitable means, as further described herein. Activity may be provided for example by introducing to a host cell or patient a vector containing a nucleotide sequence of SEQ ID No 149, treating said cell with a compound capable of increasing the expression of the polypeptide of the invention and/or treating a cell or patient directly with a polypeptide of SEQ ID No 390. In preferred embodiments, the polypeptide of the invention comprises at least one amino

35 acid substitution, deletion or insertion. In one aspect, such amino acid changes are preferably in the catalytic site; preferably said amino acid changes involve the substitution, deletion or insertion of a

His residue and preferably said amino acid changes increase the CO₂ hydration activity of the polypeptide of the invention.

Metal ion biosensors

In further aspects, metal ion biosensors can be designed based on the polypeptide of SEQ

- 5 ID No 390. Determination of metal ion concentrations in complex media such as serum, cell cytoplasm as well as for example seawater are important analytical functions that require high degrees of sensitivity and selectivity.

Biosensors may be particularly useful in detecting metal ion fluxes in and between cells. Such biosensors may exploit metal-binding ability of the polypeptide of the invention, as described
10 by Thompson et al., who have developed such biosensors based on the CA enzyme (CA II). Such biosensors are useful in the detection of metal ion flux for example in the central nervous system. Zinc-containing neurons found throughout the mammalian cerebral cortex, striatum and amygdalar nuclei have been shown to release their zinc in a depolarization- and calcium-dependent fashion in vitro and in vivo. This zinc release has been suggested to act as a trans-synaptic neuromodulator :
15 which has in turn been linked to excitotoxic neuronal cell death. CA based biosensors developed by Thompson et al. showed that zinc is present and can be detected in extracellular medium from neurons. (Thompson et al, J. Neurosci Methods 96:35-45 (2000)).

Biosensors based on CA have been shown to be extremely selective, detecting Cu at subpicomolar levels, which is of sensitivity that might be achieved with mass spectrometric
20 techniques. Sensors based on the CA II isozyme have been shown to detect Zn and Cu at picomolar levels, and Cd, Co and Ni at nanomolar levels. (Thompson et al., Anal. Biochem. 267:185-195 (1999)). CA based biosensors have also demonstrated selectivity over potential interferents in biological systems at mM levels in extracellular fluids, such as Mg and Ca. (Thompson et al. (2000), supra).

25 Biosensors based on the polypeptide of the invention are based on the high selectivity and sensitivity of CA isozymes for zinc. Because the binding of Zn in the active site of the enzyme affects the enzyme's ability to bind a CA inhibitor, it is possible to use a CA inhibitor that exhibits a detectable change upon binding to the polypeptide of the invention to detect the fraction of polypeptide bound to the inhibitor, and therefore bound to Zn. The fraction of polypeptide with
30 bound Zn in turn is determined by the concentrations of free Zn and the polypeptide of the invention, and the dissociation constant for zinc.

In one example, binding of the CA inhibitor to the polypeptide of the invention is detected by using a fluorescent inhibitor, whereby the inhibitor shows a detectable change in fluorescence emission wavelength of polarization upon binding to the polypeptide of the invention. In one
35 example, a fluorescent sulfonamide is used, such as the fluorophore ABD-N (Thompson et al. (2000), supra).

Engineered CA enzymes

CA isozymes have been shown to have differing levels of catalytic activity and efficiency. In preferred embodiments, particularly for treatments which involve providing the increased activity of the polypeptide of SEQ ID No 390 or for use in metal ion biosensors, the polypeptide of the invention may be modified for increased CO₂ hydration and/or zinc binding.

- 5 In particular, studies have been carried out characterizing residues important for maximal CA activity, allowing CA isozymes to be designed having desired levels of activity. Important structural elements in CA isozymes for zinc binding, CO₂ hydration activity and stability are reviewed in Lindskog, Pharmacol. Ther. 74(1):1-20 (1997) and Sly (1995), supra. In one example, studies of CA III showed that changing the Phe198 residue to a Leu198 residue (as in CAII)
- 10 resulted in a 25 fold increase in activity. (Chen et al., (1993), supra). Catalysis has also been greatly increased in CA II by replacing the Thr200 residue with His, as is normally found in CA I enzymes. Most dramatically, a CA-related protein (CA-RP) which in its native form was missing important residues at the catalytic site and had no detectable CO₂ hydration activity at all was rendered an active CA by only two point mutations. (Sjoblom et al., FEBS Lett. 398: 322-325(1996)).
- 15 Thus, in embodiments where the polypeptide of the invention is used to provide a source of CO₂ hydration or for its zinc binding properties, it is advantageous to modify the polypeptide of the invention by introducing at least one amino acid substitution, deletion or insertion. In one aspect, such amino acid changes are preferably in the catalytic site; preferably said amino acid changes involve the substitution, deletion or insertion of a His residue and preferably said amino acid
- 20 changes increase the CO₂ hydration activity of the polypeptide of the invention. Optimal amino acid changes can be determined by the skilled artisan, particularly in view of sequence comparisons which can be carried out with the many well-characterized CA isozymes.

Protein of SEQ ID NO:252 (internal designation 105-089-3-0-G10-CS)

- The protein of SEQ ID NO:252 is encoded by the cDNA of SEQ ID NO:11. Accordingly,
- 25 it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:252 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 105-089-3-0-G10-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:11 described throughout the present application also pertain to the human cDNA of clone 105-089-3-0-G10-CS. It is over represented in fetal brain.
- 30 The protein of SEQ ID NO:252 encoded by the cDNA of SEQ ID NO:11 is distributed primarily in the prostate and salivary gland. The protein of SEQ ID NO:252 is homologous to sequences described in PCT publication WO9827205-A2 (which describes a protein that was isolated from a human adult salivary gland cDNA library), PCT publication WO9839446-A2, PCT publication WO9839446-A2. The disclosures of each of the preceding PCT publications is
- 35 incorporated herein by reference in their entireties.

The protein of SEQ ID NO:252 is also homologous to a polypeptide described in PCT publication WO9835229-A1, the disclosure of which is incorporated herein by reference in its entirety. WO9835229-A1 describes a peptide of 27 amino acid residues that corresponds to 23/27 of a portion of the protein of SEQ ID NO:252 (amino acid 20-46). This corresponds to 85% identity with conserved changes (3 out of 4) yielding a 96% homology.

The protein described in WO 9835229 was identified in reflex tears that were collected from 12 non-contact lens wearing male and female humans. Reflex tears were stimulated by gently rubbing the nasal mucosa with a cotton wool tipped bud. Two different batches were collected from two different groups and examined by analytical and preparative 2-dimensional electrophoresis. After separation in the second dimension and transfer to PVDF membranes, identified protein spots (by 0.1% (w/v) Coomassie Blue) were loaded into a membrane-compatible Hewlett-Packard cartridge. Sequencing was conducted with a Model G1005A (Hewlett-Packard, CA) sequenator. One of the proteins identified migrated at 25 kDa and was revealed to have 5 isoforms of different pI. Two of these were N-terminally sequenced and gave the sequence of the above peptide with a pI of 5.0 and 4.4. The different isoforms indicate that this protein undergoes post-translational modifications, including sialylation or acylation. The presence of these isoforms in different degrees could reflect the disease status of the individual. Accordingly, one embodiment of the present invention relates to the detection or diagnosis of disease by determining the activity or level of the protein of SEQ ID NO:252 or a polynucleotide encoding the protein of SEQ ID NO:252 in an individual. For example, detection of the secreted protein of SEQ ID NO:252 in an individual may be accomplished non-invasively by measuring protein levels in bodily fluids into which the protein is secreted, such as tears and saliva. Such methods may be employed both in humans and in animals. It is probable that after the signal peptide is cleaved, the protein of SEQ ID NO:252 is secreted into bodily fluids including tears and probably saliva.

The protein of SEQ ID NO:252 can also be used for the screening of non-ocular diseases, by analyzing tears for marker proteins, particularly indicative of cancer and genetic disease. In addition, an altered chromatographic profile (e.g. 2D gel) of the isoforms of the protein of SEQ ID NO:252 may also indicate the disease state of an individual. For example, the levels of marker proteins in relation to the protein of SEQ ID NO:252 may be determined to evaluate whether the individual is suffering from a disease. Alternatively, tears may be analyzed for the levels of different isoforms of the protein of SEQ ID NO:252 to determine whether the pattern of such isoforms is indicative of disease.

The protein of SEQ ID NO:252 or fragments thereof may also be used as a lubricant or cleansing agent for the eyes. This protein can be included in contact lenses washing and storage solutions. This protein can also be useful as an ingredient in eye washing solutions (e.g. eye drops) used for everyday redness or healing after surgical/laser intervention. For example, the protein may be used to reduce eye inflammation. Alternatively, anti-bacterial properties may be exploited by

including the protein of SEQ ID NO:252 or fragments thereof in solutions, creams or ointments for the eyes, as well as creams or ointments in general for external applications.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:252, fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. In such embodiments, the protein of SEQ ID NO:252, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:252. The protein of SEQ ID NO:252 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:252 or a fragment thereof may be administered to the individual.

Alternatively, an agent which increases the activity of the protein of SEQ ID NO:252 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:252 or a cell or preparation containing the protein of SEQ ID NO:252 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:252 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:252 may be identified by contacting the protein of SEQ ID NO:252 or a cell or preparation containing the protein of SEQ ID NO:252 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify the source of a sample as, for example, saliva or tears, or to distinguish between two or more possible sources of a sample on the basis of the level of the protein of SEQ ID NO:252 in the sample. For example, the protein of SEQ ID NO:252 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from saliva or tears or tissues other than saliva or tears to determine whether the test sample is from saliva or tears. Alternatively, the level of the protein of SEQ ID NO:252 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:252 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ

hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from saliva or tears or tissues other than saliva or tears to determine whether the test sample is
5 from saliva or tears.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:252, including using methods known to those skilled in the art. For example, an antibody against the protein of SEQ ID NO:252 or a fragment thereof may be fixed to a solid support, such as a
10 chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:252 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:252 or a
15 fragment thereof thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:252. In such techniques, the level of the protein of SEQ ID NO:252 in an ill individual is measured using techniques such as those described herein. The level of the protein of 252 in the ill individual is compared to the level in normal individuals to determine whether the individual has a level of the protein of SEQ ID NO:252 which is indicative of disease.

20 Protein of SEQ ID NO:308 (internal designation 187-41-0-0-i21-CS)

The protein of SEQ ID NO:308 is encoded by the cDNA of SEQ ID NO:67. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:308 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 187-41-0-0-i21-CS. In addition, it will be appreciated that all characteristics and
25 uses of the nucleic acid of SEQ ID NO:67 described throughout the present application also pertain to the human cDNA of clone 187-41-0-0-i21-CS.

The protein of SEQ ID NO:308 is highly homologous to human secreted protein nf87_1 from PCT publication WO 9935252-A2 (the disclosure of which is incorporated herein by reference in its entirety), to amino acids 26-129 of the human secreted protein SEQ ID NO:441 from PCT
30 publication WO 9906548-A2 (the disclosure of which is incorporated herein by reference in its entirety), and to amino acids 26-114 of human secreted protein SEQ ID NO:439 from PCT publication WO 9906548-A2, the disclosure of which is incorporated herein by reference in its entirety. Thus, the protein of the invention appears to be a polymorphic variant of nf87_1. Since most of the proteins with high homology to the sequence of the invention have longer 5'termini, it
35 is conceivable that the protein of the invention is a truncated/spliced variant of these proteins.

The protein of SEQ ID NO:308 was identified among the cDNAs from a library constructed from brain. Tissue distribution analysis through a BLAST analysis of databases shows that mRNA encoding this protein was found primarily in kidney, liver, and cancerous prostate.

The protein of SEQ ID NO:308 has chemical and structural homology to human interferon-inducible (IFI) protein isoforms p27 (63%), HIFI (50% identity), and to interferon-induced protein 6-16 precursor (IFI-6-16, 36%). Furthermore, the protein of the invention has structural homology (40% identity) to the human erythropoietin (EPO) primary response gene, EPRG3pt from PCT publication WO 9906063-A2, the disclosure of which is incorporated herein by reference in its entirety. Thus, the present invention relates to nucleic acid and amino acid sequences of a novel IFI protein and to the use of these sequences in the diagnosis, study, prevention and treatment of disease.

The protein of SEQ ID NO:308 comprises 105 amino acids. From the amino acid alignments and the hydrophobicity plots, it has a predicted signal peptide sequence spanning residues 31-43 and two predicted transmembrane domains spanning residues 17-37, and 48-68. Accordingly, one embodiment of the present invention is a polypeptide comprising the signal peptide and/or one or more of the transmembrane domains.

Interferons (IFNs) are a part of the group of intercellular messenger proteins known as cytokines. α -IFN is the product of a multigene family of at least 16 members, whereas β -IFN is the product of a single gene. α - and β -IFNs are also known as type I IFNs. Type I IFNs are produced in a variety of cells types. Biosynthesis of type I IFNs is stimulated by viruses and other pathogens, and by various cytokines and growth factors. γ -IFN, also known as type II IFN, is produced in T-cells and natural killer cells. Antigens to which the organism has been sensitized stimulate biosynthesis of type II IFN. Both α - and γ -IFNs are immunomodulators and anti-inflammatory agents, activating macrophages, T-cells and natural killer cells.

IFNs are part of the body's natural defense to viruses and tumors. They exert these defenses by affecting the function of the immune system and by direct action on pathogens and tumor cells. IFNs mediate these multiple effects in part by inducing the synthesis of many cellular proteins. Some interferon-inducible (IFI) genes are induced equally well by α -, β - and γ -IFNs. Other IFI genes are preferentially induced by the type I or by the type II IFNs. The various proteins produced by IFI genes possess antitumor, antiviral and immunomodulatory functions. The expression of tumor antigens in cancer cells is increased by α -IFN, and renders the cancer cells more susceptible to immune rejection. The IFI proteins synthesized in response to viral infections are known to inhibit viral functions such as cell penetration, uncoating, RNA and protein synthesis, assembly and release (Hardman JG et al 25 (1996) The Pharmacological Basis of Therapeutics, McGraw-Hill, New York NY pp 1211-1214, the disclosure of which is incorporated herein by reference in its entirety). Type II IFN stimulates expression of major histocompatibility complex (MHC) proteins and is thus used in immune response enhancement.

The IFI gene known as 6-16 encodes an mRNA, which is highly induced by type I IFNs in a variety of human cells (Kelly JM et al (1986) EMBO J 5:1601-1606, the disclosure of which is incorporated herein by reference in its entirety). After induction, 6-16 mRNA constitutes as much as 0.1% of the total cellular mRNA. The 6-16 mRNA is present at only very low levels in the
5 absence of type I IFN, and is only weakly induced by type II IFN. The 6-16 mRNA encodes a hydrophobic protein of 130 amino acids. The first 20 to 23 amino acids comprise a putative signal peptide. Protein 6-16 has at least two predicted transmembrane regions culminating in a negatively charged C-terminus.

The p27 gene encodes a protein with 41% amino acid sequence identity to the 6-16 protein.
10 The p27 gene is expressed in some breast tumor cell lines and in a gastric cancer cell line. In other breast tumor cell lines, in the HeLa cervical cancer cell line, and in fetal lung fibroblasts, p27 expression occurs only upon α -IFN induction. In one breast tumor cell line, p27 is independently induced by estradiol and by IFN (Rasmussen UB et al (1993) Cancer Res 53:4096-4101, the disclosure of which is incorporated herein by reference in its entirety). Expression of p27 was
15 analyzed in 21 primary invasive breast carcinomas, 1 breast cancer bone metastasis, and 3 breast fibroadenomas. High levels of p27 were found in about one-half of the primary carcinomas and in the bone metastasis, but not in the fibroadenomas. These observations suggest that certain breast tumors may produce high levels of, or have increased sensitivity to, type I IFN as compared to other breast tumors (Rasmussen UB et al, supra). In addition, the p27 gene expressed at significant levels
20 in normal tissues including colon, stomach and lung, but not expressed in placenta, kidney, liver or skin. (Rasmussen UB et al, supra).

The small hydrophobic IFI gene products may contribute to viral resistance. A hepatitis-C virus (HCV)-induced gene, 130-51, was isolated from a cDNA library prepared from chimpanzee liver during the acute phase of the infection. The protein product of this gene has 97% identity to
25 the human 6-16 protein (Kato T et al (1992) Virology 190:856-860, the disclosure of which is incorporated herein by reference in its entirety). The authors of the preceding paper suggest that HCV infection actively induces IFN expression, which in turn induces expression of IFI genes including 130-51. The IFI proteins synthesized in response to viral infections are known to inhibit viral functions such as penetration, uncoating, RNA or protein synthesis, assembly or release. The
30 130-51 protein may inhibit one or more of these functions in HCV. A particular virus may be inhibited in multiple functions by IFI proteins. In addition, the principle inhibitory effect exerted by IFI proteins differs among the virus families (Hardman JG, supra, p 1211, the disclosure of which is incorporated herein by reference).

The HIFI protein (PCT publication WO 9812223-A2, the disclosure of which is
35 incorporated herein by reference in its entirety) is a human sequence identified among cDNAs from a library constructed from human neonatal kidney. Northern blot analysis using LIFESEQ™ database (Incyte Pharmaceuticas, Palo Alto, CA) shows that HIFI mRNA was found only in

neonatal kidney. The HIFI protein consists of 104 amino acids and has 55%, 45%, and 46% amino acid sequence identity to p27, 6-16 and 130-51, respectively.

Based on the chemical and structural homology between the protein of SEQ ID NO:308 and the small hydrophobic IFI proteins from human and chimpanzee, it is believed that the protein of SEQ ID NO:308 is synthesized when interferons are produced in infections, inflammation, autoimmune diseases etc. Interferons are produced in response to various cytokines and growth factors, in viral infections, inflammation, autoimmune diseases, and cancers. Accordingly, the protein of SEQ ID NO:308 or fragments thereof may be used in diagnosis and treatment of diseases such as, but not limited to, autoimmune disorders such as rheumatoid arthritis, Graves disease, systemic lupus erythematosus, autoimmune hepatitis, Wegener's granulomatosis, sarcoidosis, polyarthritis, pemphigus, pemphigoid, erythema multiform, Sjogren's syndrome, inflammatory bowel disease, multiple sclerosis, myasthenia gravis keratitis, scleritis, Type I diabetes, insulin-dependent diabetes mellitus, Lupus Nephritis, and allergic encephalomyelitis; proliferative disorders including various forms of cancer such as leukemias, lymphomas (Hodgkins and non-Hodgkins), sarcomas, melanomas, adenomas, carcinomas of solid tissue, hypoxic tumors, squamous cell carcinomas of the mouth, throat, larynx, and lung, genitourinary cancers such as cervical and bladder cancer, hematopoietic cancers, head and neck cancers, and nervous system cancers, benign lesions such as papillomas, atherosclerosis, angiogenesis; viral infections, in particular HCV and HIV infections, as well as other pathogen-induced infections (e.g. leishmania).

The protein of SEQ ID NO:308 or fragments thereof may also be used to treat conditions associated with inflammation or immune impairment (e. g. reumathoid and osteo arthritis and AIDS).

Another embodiment of the present invention relates to the use of the protein of SEQ ID NO:308 or fragments thereof to treat and/or prevent the ill-effect of bacterial infection during pregnancy in mammals, such as spontaneous abortion and maternal death. In a preferred embodiment, the protein of the invention may be used to counteract the effects of the bacterial endotoxin lipopolysaccharide (LPS). The methods for using such compositions is described in Dziegielewska and Andersen, Biol. Neonate, 74:372-5 (1998), the disclosure of which is incorporated herein by reference in its entirety.

Furthermore, the protein of SEQ ID NO:308 or fragments thereof are useful as a reagent for analyzing the control of gene expression by interferons and other cytokines in both normal and diseased cells. The protein of the SEQ ID NO:308 or fragments thereof may be used to identify specific molecules with which it binds such as agonists, antagonists or inhibitors.

Another embodiment of the present invention relates to methods of using the protein of SEQ ID NO:308 or fragments thereof to identify and/or quantify cytokines of the interferon family as well as other cytokines such as IL10 and tumor antigens, which may interact with the protein of the invention.

The protein of SEQ ID NO:308 or fragments thereof may also be included in pharmaceutical preparations for treating cancer or prevention/treatment of other diseases associated with changes in expression of the protein of the invention. In another embodiment of the present invention, the protein of SEQ ID NO 308 or fragments thereof is used to inhibit and/or modulate the effect of cytokines and related molecule such as Il-2, TNF alpha, CTLA4, CD28, and others, by preventing the binding of the endogenous cytokine to their natural receptors, thereby blocking cell proliferation or inhibitory signals generated by the ligand-receptor binding event.

The protein of SEQ ID NO:308 or fragments thereof is useful to correct defects in in vivo models of disease such as autoimmune, inflammation and tumor models, by injecting the protein either intra peritoneally intravenously, subcutaneously or directly in the diseased tissue.

The DNA encoding the protein of SEQ ID NO:308 or fragments thereof is useful in diagnostic assays for conditions/diseases associated with expression of the protein of the invention. The diagnostic assay is useful to distinguish between absence, presence, and excess expression of the protein of the invention and to monitor regulation of levels of the protein of the invention during therapeutic intervention. The DNA may also be incorporated into effective eukaryotic expression vectors and directly targeted to a specific tissue, organ, or cell population for use in gene therapy to treat the above mentioned conditions, including tumors and/or to correct disease- or genetic-induced defects in any of the above mentioned proteins including the protein of the invention. The DNA may also be used to design antisense sequences and ribozymes, which can be administered to modify gene expression in tumor and pathogen-infected cells and to influence expression of cytokines and growth factors. In vivo delivery of genetic constructs into subjects can be developed to the point of targeting specific cell types, such as tumor where expression of the protein of the invention may be affected or is modulating the expression and/or activity of other proteins such as cytokines, growth factors, their receptors and/or tumor antigens. It is also useful to detect unknown upstream sequences (e. g. promoters and regulatory elements) by standard techniques and for research into the control of gene expression by interferons and other cytokines, as well as growth and transcription factors in normal and diseased cells. Hybridization probes are useful to detect DNA encoding the protein of the invention (or closely related molecules) in biological samples, and for mapping the naturally occurring genomic sequence to a particular chromosome/chromosome region. The DNA may be used to generate and/or treat in vivo animal models of disease, including susceptibility or resistance to infection, inflammation, tumors and autoimmune conditions, as well as tumor therapy, based on vaccine, knock-out and transgene technologies.

Antibodies against the protein of SEQ ID NO:308 or fragments thereof are useful for the diagnosis of conditions and diseases associated with its expression and to quantify the protein of the invention (e. g. in assays to monitor patients during therapeutic intervention). Antibodies specific for the protein may include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab fragments produced by a Fab expression library. Neutralizing antibodies are especially

preferred for diagnostics and therapeutics. Diagnostic assays for the protein of the invention include methods utilizing the antibody and a label to detect the protein of the invention in human body fluids or extracts of cells or tissues.

The protein of the invention and its catalytic or immunogenic fragments or oligopeptides thereof, can be used for screening therapeutic compounds in any variety of drug screening techniques including high throughput. Methods which may be used to quantitate the expression of the nucleotide or protein of the invention include, but are not limited to, polymerase chain reaction (PCR), RT-PCR, RNase protection, Northern and western blotting, enzyme-linked immunosorbent assay (ELISA), radioimmunoassay (RIA), fluorescent activated cell sorting (FACS), immunoprecipitation, and chromatography.

Under conditions of significant blood loss, EPO therapy, or both, iron-restricted erythropoiesis is evident. However, intravenous or oral iron therapy has substantial drawbacks. Moreover, traditional biochemical markers of storage iron in patients with anemia of chronic disease are unhelpful in the assessment of iron status (Lawrence T et al (2000) Blood 96:823-833, the disclosure of which is incorporated herein by reference in its entirety). As the protein of SEQ ID NO:308 bears homology to the human erythropoietin (EPO) primary response gene, EPRG3pt, it may be used to promote red blood cell formation or to monitor the value of safer intravenous iron preparations in patients with blood loss anemia, particularly those undergoing EPO therapy.

The hydrophobic IFI protein of SEQ ID NO:308 or fragments thereof may be used to diagnose conditions associated with its induction. For example, the protein of SEQ ID NO:308 or fragments thereof may be useful in the diagnosis and treatment of tumors, viral infections, inflammation, or conditions associated with impaired immunity, anemia of chronic blood loss or chronic disease, hemochromatosis, and EPO therapy. Furthermore, this protein may be used for investigating the control of gene expression by IFNs and other cytokines, as well as hormones and growth factors, in normal and diseased cells.

The protein of SEQ ID NO:308 or fragments thereof is useful to correct defects in in vivo models of disease such as autoimmune, inflammation, anemia, iron-overload and tumor models, by injecting the protein either intra peritoneally intravenously, subcutaneously or directly in the diseased tissue.

In addition, the protein of SEQ ID NO:308 is structurally related to other proteins having homology and/or structural similarity with human p27 (Rasmussen, U.B., et al., 1993, Cancer Research 53:4096-4101, the disclosure of which is incorporated herein by reference). Accordingly, the protein of brain, fetal brain, kidney, fetal kidney, or colon may be used to regulate the proliferation of EPO-dependent cells or the growth and development of erythroid and other hematopoietic lineages.

The protein of SEQ ID NO:308 or fragments thereof, or polynucleotides encoding the protein of SEQ ID NO:308 or fragments thereof, may be used to treat or ameliorate anemia of

chronic disease and chronic renal failure, polycythemia, cancer, AIDS, drug- and phlebotomy-induced anemias, hemochromatosis, erythropoiesis mediated by EPO therapy, and other conditions associated with altered activity or levels of the protein of SEQ ID NO:308.

In another embodiment, the present invention relates to methods for identifying agonists and antagonists/inhibitors using the protein of SEQ ID NO:308 or fragments thereof, and treating conditions with the identified compounds. In a still further aspect, the invention relates to diagnostic assays for detecting diseases associated with inappropriate levels or activity of the protein of SEQ ID NO:308. In still another embodiment of the invention relates to the use of the protein SEQ ID NO:308, fragments thereof or the DNA encoding the protein of SEQ ID NO:308 or fragments thereof to monitor the value of iron therapy in patients undergoing EPO therapy, or experiencing blood loss, or both.

The DNA encoding the protein of SEQ ID NO:308 or fragments thereof is useful in diagnostic assays for conditions/diseases associated with abnormal expression of the protein of SEQ ID NO:308. The diagnostic assay is useful to distinguish between absence, presence, and excess expression of the protein of the invention and to monitor regulation of levels of the protein of the invention during therapeutic intervention. The DNA may also be incorporated into effective eukaryotic expression vectors and directly targeted to a specific tissue, organ, or cell population for use in gene therapy to treat the above mentioned conditions, including tumors and/or to correct disease- or genetic-induced defects in any of the above mentioned proteins including the protein of the invention. The DNA may also be used to design antisense sequences and ribozymes, which can be administered to modify gene expression in tumor and pathogen-infected cells and to influence expression of cytokines, hormones and growth factors. In vivo delivery of genetic constructs into subjects can be developed to the point of targeting specific cell types, such as tumor where expression of the protein of the invention may be affected or is modulating the expression and/or activity of other proteins such as cytokines, growth factors, their receptors and/or tumor antigens. It is also useful to detect unknown upstream sequences (e. g. promoters and regulatory elements) by standard techniques and for research into the control of gene expression by interferons and other cytokines, as well as growth and transcription factors in normal and diseased cells. Hybridization probes are useful to detect DNA encoding the protein of the invention (or closely related molecules) in biological samples, and for mapping the naturally occurring genomic sequence to a particular chromosome/chromosome region. The DNA may be used to generate and/or treat in vivo animal models of disease, including susceptibility or resistance to infection, tumors, autoimmune conditions, anemia and iron-overload, as well as tumor therapy, based on vaccine, knock-out and transgene technologies.

Antibodies against the protein of SEQ ID NO:308 are useful for the diagnosis of conditions and disease associated with its expression and to quantify the protein of the invention (e. g. in assays to monitor patients during therapeutic intervention). Antibodies specific for the protein may

include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab fragments produced by a Fab expression library. Neutralizing antibodies are especially preferred for diagnostics and therapeutics. Diagnostic assays for the protein of SEQ ID NO:308 include methods utilizing the antibody and a label to detect the protein of the invention in human body fluids or
5 extracts of cells or tissues.

The protein of SEQ ID NO:308 and its catalytic or immunogenic fragments or oligopeptides thereof, can be used for screening therapeutic compounds in any variety of drug screening techniques including high throughput. Methods which may be used to quantitate the expression of the nucleotide or protein of the invention include, but are not limited to, polymerase chain reaction
10 (PCR), RT-PCR, RNase protection, Northern blotting, enzyme-linked immunosorbent assay (ELISA), radioimmunoassay (RIA), fluorescent activated cell sorting (FACS), immunoprecipitation, and chromatography.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:308, fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200
15 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. For example, the condition may be cancer, including breast cancer, viral infection, bacterial infection, inflammation, autoimmune disorders, rheumatoid arthritis, Graves disease, systemic lupus erythematosus, autoimmune hepatitis, Wegener's granulomatosis, sarcoidosis, polyarthritis, pemphigus, pemphigoid, erythema multiform, Sjogren's
20 syndrome, inflammatory bowel disease, multiple sclerosis, myasthenia gravis keratitis, scleritis, Type I diabetes, insulin-dependent diabetes mellitus, Lupus Nephritis, and allergic encephalomyelitis; proliferative disorders including various forms of cancer such as leukemias, lymphomas (Hodgkins and non-Hodgkins), sarcomas, melanomas, adenomas, carcinomas of solid tissue, hypoxic tumors, squamous cell carcinomas of the mouth, throat, larynx, and lung,
25 genitourinary cancers such as cervical and bladder cancer, hematopoietic cancers, head and neck cancers, and nervous system cancers, benign lesions such as papillomas, atherosclerosis, angiogenesis; viral infections, in particular HCV and HIV infections, as well as other pathogen-induced infections (e. g. leishmania).

In such embodiments, the protein of SEQ ID NO:308, or a fragment thereof, is
30 administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:308. The protein of SEQ ID NO:308 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:308 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:308 may be administered to the
35 individual. Such agents may be identified by contacting the protein of SEQ ID NO:308 or a cell or preparation containing the protein of SEQ ID NO:308 with a test agent and assaying whether the

test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:308 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:308 may be identified by contacting the protein of
5 SEQ ID NO:308 or a cell or preparation containing the protein of SEQ ID NO:308 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

10 In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify the source of a sample as, for example, brain, kidney, liver, or cancerous prostate, or to distinguish between two or more possible sources of a sample on the basis of the level of the protein of SEQ ID NO:308 in the sample. For example, the protein of SEQ ID NO:308 or fragments thereof may be used to generate antibodies
15 using any techniques known to those skilled in the art, including those described therein. Such antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate
20 antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from brain, kidney, liver, or cancerous prostate or tissues other than brain, kidney, liver, or cancerous prostate to determine whether the test sample is from brain, kidney, liver, or cancerous prostate. Alternatively, the level of the protein of SEQ ID NO:308 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID
25 NO:308 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from brain, kidney, liver, or cancerous prostate or tissues
30 other than brain, kidney, liver, or cancerous prostate to determine whether the test sample is from brain, kidney, liver, or cancerous prostate.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:308, including using methods known to those skilled in the art. For example, an antibody against the
35 protein of SEQ ID NO:308 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:308 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The

support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:308 or a fragment thereof thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:308. In such techniques, the level of the protein of SEQ ID NO:308 in an ill individual is measured using techniques such as those described herein. The level of the protein of SEQ ID NO:308 in the ill individual is compared to the level in normal individuals to determine whether the individual has a level of the protein of SEQ ID NO:308 which is associated with disease.

10 Protein of SEQ ID NOs:289 and 307 (internal designations 175-1-3-0-E5-CS.cor and 187-39-0-0-k12-CS)

The protein of SEQ ID NO:289 is encoded by the cDNA of SEQ ID NO:48. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:289 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 175-1-3-0-E5-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:48 described throughout the present application also pertain to the human cDNA of clone 175-1-3-0-E5-CS.

The protein of the invention consists of 130 amino acids. From the amino acid alignments and the hydrophobicity plots, it has a predicted signal peptide sequence spanning residues 8-20 and four predicted transmembrane domains spanning residues 2-24, 42-61, 70-90 and 99-119. Accordingly, some embodiments of the present invention relate to polypeptides comprising the signal peptide and/or one or more of the transmembrane domains.

The protein of SEQ ID NO:289 encoded by the cDNA of SEQ ID NO:48 is homologous to SEQ ID NO: 4199 from EP 1033401-A2 (the disclosure of which is incorporated herein by reference in its entirety), a human secreted protein. Another protein, SEQ ID NO:307, encoded by the cDNA of SEQ ID NO:66, is a polymorphic variant of the protein of SEQ ID NO:289, and shares all of the herein-described functions and uses.

The present invention relates to a novel protein identified among the cDNAs from a library constructed from salivary gland, and to the use of the nucleic acid and amino acid sequences disclosed herein in the study, diagnosis, prevention, and treatment of disease. Tissue distribution analysis predicted by BLAST on databases shows that mRNA encoding this protein was found primarily in brain and fetal brain, with lower amounts in kidney, fetal kidney and colon.

Interferons (IFNs) are a part of the group of intercellular messenger proteins known as cytokines. α -IFN is the product of a multigene family of at least 16 members, whereas b-IFN is the product of a single gene. α - and β -IFNs are also known as type I IFNs. Type I IFNs are produced in a variety of cells types. Biosynthesis of type I IFNs is stimulated by viruses and other pathogens,

and by various cytokines and growth factors. γ -IFN, also known as type II IFN, is produced in T-cells and natural killer cells. Antigens to which the organism has been sensitized stimulate biosynthesis of type II IFN. Both α - and γ -IFNs are immunomodulators and anti-inflammatory agents, activating macrophages, T-cells and natural killer cells.

5 IFNs are part of the body's natural defense to viruses and tumors. They exert these defenses by affecting the function of the immune system and by direct action on pathogens and tumor cells. IFNs mediate these multiple effects in part by inducing the synthesis of many cellular proteins. Some interferon-inducible (IFI) genes are induced equally well by α -, β - and γ -IFNs. Other IFI genes are preferentially induced by the type I or by the type II IFNs. The various proteins produced
10 by IFI genes possess antitumor, antiviral and immunomodulatory functions. The expression of tumor antigens in cancer cells is increased by α -IFN, and renders the cancer cells more susceptible to immune rejection. The IFI proteins synthesized in response to viral infections are known to inhibit viral functions such as cell penetration, uncoating, RNA and protein synthesis, assembly and release (Hardman JG et al 25 (1996) *The Pharmacological Basis of Therapeutics*, McGraw-Hill,
15 New York NY pp 1211-1214, the disclosure of which is incorporated herein by reference in its entirety). Type II IFN stimulates expression of major histocompatibility complex (MHC) proteins and is thus used in immune response enhancement.

The protein of SEQ ID NO:289 is a small hydrophobic protein having chemical and structural homology to human interferon-inducible (IFI) protein isoforms 6-16 (97% identity), HIFI
20 (44%), and p27 (33%), as well as 130-51, the chimpanzee homolog of 6-16 - (97%). Thus, the protein of SEQ ID NO:289 and the nucleic acid encoding it are polymorphic variants of 6-16 or the gene encoding 6-16. The protein of SEQ ID NO:289, fragments thereof, or nucleic acids encoding the protein of SEQ ID NO:289 or fragments thereof may be used in the diagnosis, study, prevention and treatment of disease as described below.

25 The IFI gene known as 6-16 encodes an mRNA, which is highly induced by type I IFNs in a variety of human cells (Kelly JM et al (1986) *EMBO J* 5:1601-1606, the disclosure of which is incorporated herein by reference in its entirety). After induction, 6-16 mRNA constitutes as much as 0.1% of the total cellular mRNA. The 6-16 mRNA is present at only very low levels in the absence of type I IFN, and is only weakly induced by type II IFN. The 6-16 mRNA encodes a hydrophobic
30 protein of 130 amino acids. The first 20 to 23 amino acids comprise a putative signal peptide. Protein 6-16 has at least two predicted transmembrane regions culminating in a negatively charged C-terminus.

The p27 gene encodes a protein with 41% amino acid sequence identity to the 6-16 protein. The p27 gene is expressed in some breast tumor cell lines and in a gastric cancer cell line. In other
35 breast tumor cell lines, in the HeLa cervical cancer cell line, and in fetal lung fibroblasts, p27 expression occurs only upon α -IFN induction. In one breast tumor cell line, p27 is independently induced by estradiol and by IFN (Rasmussen UB et al (1993) *Cancer Res* 53:4096-4101, the

disclosure of which is incorporated herein by reference in its entirety). Expression of p27 was analyzed in 21 primary invasive breast carcinomas, 1 breast cancer bone metastasis, and 3 breast fibroadenomas. High levels of p27 were found in about one-half of the primary carcinomas and in the bone metastasis, but not in the fibroadenomas. These observations suggest that certain breast
5 tumors may produce high levels of, or have increased sensitivity to, type I IFN as compared to other breast tumors (Rasmussen UB et al, supra). In addition, the p27 gene expressed at significant levels in normal tissues including colon, stomach and lung, but not expressed in placenta, kidney, liver or skin. (Rasmussen UB et al, supra).

The small hydrophobic IFI gene products may contribute to viral resistance. A hepatitis-C
10 virus (HCV)-induced gene, 130-51, was isolated from a cDNA library prepared from chimpanzee liver during the acute phase of the infection. The protein product of this gene has 97% identity to the human 6-16 protein (Kato T et al (1992) Virology 190:856-860, the disclosure of which is incorporated herein by reference in its entirety). The authors of this paper suggest that HCV infection actively induces IFN expression, which in turn induces expression of IFI genes including
15 130-51. The IFI proteins synthesized in response to viral infections are known to inhibit viral functions such as penetration, uncoating, RNA or protein synthesis, assembly or release. The 130-51 protein may inhibit one or more of these functions in HCV. A particular virus may be inhibited in multiple functions by IFI proteins. In addition, the principle inhibitory effect exerted by IFI proteins differs among the virus families (Hardman JG, supra, p 1211, the disclosure of which is
20 incorporated herein by reference).

The HIFI protein (PCT publication WO 9812223-A2, the disclosure of which is incorporated herein by reference in its entirety) is a human sequence identified among cDNAs from a library constructed from human neonatal kidney. Northern blot analysis using LIFESEQ™ database (Incyte Pharmaceuticas, Palo Alto, CA) shows that HIFI mRNA was found only in
25 neonatal kidney. The HIFI protein consists of 104 amino acids and has 55%, 45%, and 46% amino acid sequence identity to p27, 6-16 and 130-51, respectively.

The hydrophobic IFI proteins of the invention may provide the basis for clinical diagnosis of diseases associated with their induction. These proteins may be useful in the diagnosis and treatment of tumors, viral infections, inflammation, or conditions associated with impaired
30 immunity. Furthermore, these proteins may be used for investigations of the control of gene expression by IFNs and other cytokines in normal and diseased cells.

Based on the chemical and structural homology among the protein of SEQ ID NO:289 and the small hydrophobic IFI proteins from human and chimpanzee, it is believed that the protein of SEQ ID NO:289 is synthesized when interferons are produced in infections, inflammation,
35 autoimmune diseases etc. Interferons are produced in response to various cytokines and growth factors, in viral infections, inflammation, autoimmune diseases, and cancers. Accordingly, the protein of SEQ ID NO:289 or fragments thereof may be used in diagnosis and treatment of diseases

such as, but not limited to, autoimmune disorders such as rheumatoid arthritis, Graves disease, systemic lupus erythematosus, autoimmune hepatitis, Wegener's granulomatosis, sarcoidosis, polyarthritis, pemphigus, pemphigoid, erythema multiform, Sjogren's syndrome, inflammatory bowel disease, multiple sclerosis, myasthenia gravis keratitis, scleritis, Type I diabetes, insulin-
5 dependent diabetes mellitus, Lupus Nephritis, and allergic encephalomyelitis; proliferative disorders including various forms of cancer such as leukemias, lymphomas (Hodgkins and non-Hodgkins), sarcomas, melanomas, adenomas, carcinomas of solid tissue, hypoxic tumors, squamous cell carcinomas of the mouth, throat, larynx, and lung, genitourinary cancers such as cervical and bladder cancer, hematopoietic cancers, head and neck cancers, and nervous system cancers, benign
10 lesions such as papillomas, atherosclerosis, angiogenesis; viral infections, in particular HCV and HIV infections, as well as other pathogen-induced infections (e. g. leishmania).

The protein of SEQ ID NO:289 or fragments thereof may also be used to treat conditions associated with inflammation or immune impairment (e. g. reumathoid and osteo arthritis and AIDS).

15 Another embodiment of the present invention relates to the use of the protein of SEQ ID NO:289 or fragments thereof to treat and/or prevent the ill-effect of bacterial infection during pregnancy in mammals, such as spontaneous abortion and maternal death. In a preferred embodiment, the protein of the invention may be used to counteract the effects of the bacterial endotoxin lipopolysaccharide (LPS). The methods for using such compositions is described in
20 Dziegielewska and Andersen, Biol. Neonate, 74:372-5 (1998), the disclosure of which is incorporated herein by reference in its entirety.

Furthermore, the protein of SEQ ID NO:289 or fragments thereof are useful as a reagent for analyzing the control of gene expression by interferons and other cytokines in both normal and diseased cells. The protein of the SEQ ID NO:289 or fragments thereof may be used to identify
25 specific molecules with which it binds such as agonists, antagonists or inhibitors.

Another embodiment of the present invention relates to methods of using the protein of SEQ ID NO:289 or fragments thereof to identify and/or quantify cytokines of the interferon family as well as other cytokines such as IL-10 and tumor antigens, which may interact with the protein of the invention.

30 The protein of SEQ ID NO:289 or fragments thereof may also be included in pharmaceutical preparations for treating cancer or prevention/treatment of other diseases associated with changes in expression of the protein of the invention. In another embodiment of the present invention, the protein of SEQ ID NO:289 or fragments thereof is used to inhibit and/or modulate the effect of cytokines and related molecule such as Il-2, TNF alpha, CTLA4, CD28, and others, by
35 preventing the binding of the endogenous cytokine to their natural receptors, thereby blocking cell proliferation or inhibitory signals generated by the ligand-receptor binding event.

The protein of SEQ ID NO:289 or fragments thereof is useful to correct defects in in vivo models of disease such as autoimmune, inflammation and tumor models, by injecting the protein either intra peritoneally intravenously, subcutaneously or directly into the diseased tissue.

The DNA encoding the protein of SEQ ID NO:289 or fragments thereof is useful in

5 diagnostic assays for conditions/diseases associated with expression of the protein of the invention. The diagnostic assay is useful to distinguish between absence, presence, and excess expression of the protein of the invention and to monitor regulation of levels of the protein of the invention during therapeutic intervention. The DNA may also be incorporated into effective eukaryotic expression vectors and directly targeted to a specific tissue, organ, or cell population for use in gene therapy to

10 treat the above mentioned conditions, including tumors and/or to correct disease- or genetic-induced defects in any of the above mentioned proteins including the protein of the invention. The DNA may also be used to design antisense sequences and ribozymes, which can be administered to modify gene expression in tumor and pathogen-infected cells and to influence expression of cytokines and growth factors. In vivo delivery of genetic constructs into subjects can be developed

15 to the point of targeting specific cell types, such as tumor where expression of the protein of the invention may be affected or is modulating the expression and/or activity of other proteins such as cytokines, growth factors, their receptors and/or tumor antigens. It is also useful to detect unknown upstream sequences (e. g. promoters and regulatory elements) by standard techniques and for research into the control of gene expression by interferons and other cytokines, as well as growth

20 and transcription factors in normal and diseased cells. Hybridization probes are useful to detect DNA encoding the protein of the invention (or closely related molecules) in biological samples, and for mapping the naturally occurring genomic sequence to a particular chromosome/chromosome region. The DNA may be used to generate and/or treat in vivo animal models of disease, including susceptibility or resistance to infection, inflammation, tumors and autoimmune conditions, as well

25 as tumor therapy, based on vaccine, knock-out and transgene technologies.

Antibodies against the protein of SEQ ID NO:289 or fragments thereof are useful for the diagnosis of conditions and diseases associated with its expression and to quantify the protein of the invention (e. g. in assays to monitor patients during therapeutic intervention). Antibodies specific for the protein may include, but are not limited to, polyclonal, monoclonal, chimeric, single chain,

30 Fab fragments produced by a Fab expression library. Neutralizing antibodies are especially preferred for diagnostics and therapeutics. Diagnostic assays for the protein of the invention include methods utilizing the antibody and a label to detect the protein of the invention in human body fluids or extracts of cells or tissues.

The protein of the invention and its catalytic or immunogenic fragments or oligopeptides

35 thereof, can be used for screening therapeutic compounds in any variety of drug screening techniques including high throughput. Methods which may be used to quantitate the expression of the nucleotide or protein of the invention include, but are not limited to, polymerase chain reaction

(PCR), RT-PCR, RNase protection, Northern and western blotting, enzyme-linked immunosorbent assay (ELISA), radioimmunoassay (RIA), fluorescent activated cell sorting (FACS), immunoprecipitation, and chromatography.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:289, fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. For example, the condition may be cancer, including breast cancer, viral infection, bacterial infection, inflammation, autoimmune disorders, rheumatoid arthritis, Graves disease, systemic lupus erythematosus, autoimmune hepatitis, Wegener's granulomatosis, sarcoidosis, polyarthritis, pemphigus, pemphigoid, erythema multiform, Sjogren's syndrome, inflammatory bowel disease, multiple sclerosis, myasthenia gravis keratitis, scleritis, Type I diabetes, insulin-dependent diabetes mellitus, Lupus Nephritis, and allergic encephalomyelitis; proliferative disorders including various forms of cancer such as leukemias, lymphomas (Hodgkins and non-Hodgkins), sarcomas, melanomas, adenomas, carcinomas of solid tissue, hypoxic tumors, squamous cell carcinomas of the mouth, throat, larynx, and lung, genitourinary cancers such as cervical and bladder cancer, hematopoietic cancers, head and neck cancers, and nervous system cancers, benign lesions such as papillomas, atherosclerosis, angiogenesis; viral infections, in particular HCV and HIV infections, as well as other pathogen-induced infections (e. g. leishmania).

In such embodiments, the protein of SEQ ID NO:289, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:289. The protein of SEQ ID NO:289 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:289 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:289 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:289 or a cell or preparation containing the protein of SEQ ID NO:289 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:289 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:289 may be identified by contacting the protein of SEQ ID NO:289 or a cell or preparation containing the protein of SEQ ID NO:289 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify the source of a sample as, for example, brain, fetal brain, kidney, fetal kidney, or colon, or to distinguish between two or more possible sources of a sample on the basis of the level of the protein of SEQ ID NO:289 in the sample. For example, the protein of SEQ ID NO:289 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from brain, fetal brain, kidney, fetal kidney, or colon or tissues other than brain, fetal brain, kidney, fetal kidney, or colon to determine whether the test sample is from brain, fetal brain, kidney, fetal kidney, or colon. Alternatively, the level of the protein of SEQ ID NO:289 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:289 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from brain, fetal brain, kidney, fetal kidney, or colon or tissues other than brain, fetal brain, kidney, fetal kidney, or colon to determine whether the test sample is from brain, fetal brain, kidney, fetal kidney, or colon.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:289, including using methods known to those skilled in the art. For example, an antibody against the protein of SEQ ID NO:289 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:289 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:289 or a fragment thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:289. In such techniques, the level of the protein of SEQ ID NO:289 in an ill individual is measured using techniques such as those described herein. The level of the protein of SEQ ID NO:289 in the ill individual is compared to the level in normal individuals to determine whether the individual has a level of the protein of SEQ ID NO:289 which is associated with disease.

Protein of SEQ ID NO:268 (internal designation 116-111-4-0-B3-CS)

The protein of SEQ ID NO:268 is encoded by the cDNA of SEQ ID NO:27. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:268 described throughout the present application also pertain to the polypeptide encoded by the human
 5 cDNA of clone 116-111-4-0-B3-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:27 described throughout the present application also pertain to the human cDNA of clone 116-111-4-0-B3-CS. The protein of the invention is found to be expressed in testis and lungs.

The protein of SEQ ID NO:268 encoded by the extended cDNA SEQ ID NO: 27 is a
 10 splicing variant of XAGE-1, a member of the CT antigen family overexpressed in Ewing sarcoma (Liu, X. F., L. J. Helman, et al. (2000). Cancer Res 60(17): 4752-5, the disclosures of which are incorporated by reference herein in their entireties). In addition, the protein of SEQ ID NO:268 also shows strong homology at the COOH end with PAGE4, another member of the CT antigen family (Brinkmann, U., G. Vasmatazsis, et al. (1999) Cancer Res 59(7): 1445-8, the disclosure of which is
 15 incorporated herein by reference in its entirety).

The cDNA SEQ ID NO:27 is composed of 5 exons. Exon 1 lies between nucleotides 1-245, exon2 lies between nucleotides 246-370, exon 3 lies between nucleotides 371-512, exon 4 lies between nucleotides 513-639, and exon 5 lies between nucleotides 640-762 . Exons 2 to 5 of cDNA
 20 SEQ ID NO:27 are shared in part with XAGE-1. However, since the initiation codon of SEQ ID NO: 27 is located in intron1 of XAGE-1, there is a frameshift in the alignment of the 2 molecules. Exon 1 of SEQ ID NO:27 lies between nucleotides 110-234 of XAGE-1, exon 2 of SEQ ID NO:27 lies between nucleotides 235-376 of XAGE-1, exon 3 of SEQ ID NO:27 lies between nucleotides 377-503 of XAGE-1, and exon 4 of SEQ ID NO:27 lies between nucleotides 504-526 of XAGE-1.

XAGE-1 is overexpressed in sarcoma and alveolar rhabdomyosarcoma and is also highly
 25 expressed in normal testis (Liu, X. F., L. J. Helman, et al. (2000). Cancer Res 60(17): 4752-5, the disclosure of which is incorporated herein by reference in its entirety). In addition XAGE-1 share homology with PAGE-4 (Brinkmann, U., G. Vasmatazsis, et al. (1999) Cancer Res 59(7): 1445-8, the disclosure of which is incorporated herein by reference in its entirety) at the COOH end.

CT antigens are a distinct class of differentiation antigens that are expressed by cancers
 30 arising in nonessential normal tissues such as prostate, breast, and ovary (G. Vasmatazsis et al., Proc. Natl. Acad. Sci. USA, 95: 300-304, 1998, the disclosure of which is incorporated herein by reference in its entirety) and that have a restricted pattern of expression in normal tissues. This class of antigens are presented on the surface of tumor cells and are recognized by cytolytic T cells, leading to lysis. The extent to which these antigens have been studied, has been via cytolytic T cell
 35 characterization studies, in vitro i.e., the study of the identification of the antigen by a particular cytolytic T cell ("CTL" hereafter) subset. The subset proliferates upon recognition of the presented tumor rejection antigen, and the cells presenting the antigen are lysed. Characterization studies have

identified CTL clones which specifically lyse cells expressing the antigens. Examples of this work may be found in Levy et al., Adv. Cancer Res. 24: 1-59 (1977); Boon et al., J. Exp. Med. 152: 1184-1193 (1980); Brunner et al., J. Immunol. 124: 1627-1634 (1980); Maryanski et al., Eur. J. Immunol. 124: 1627-1634 (1980); Maryanski et al., Eur. J. Immunol. 12: 406-412 (1982); Palladino et al., Canc. Res. 47: 5074-5079 (1987), the disclosures of which are incorporated herein by reference in their entirety.

Some thoroughly studied CT antigens are MAGE, BAGE, GAGE and LAGE, others have been added including PAGE, XAGE, most of them located on chromosome X. Brinkmann et al reported the identification of three new members of the GAGE/ PAGE family, termed XAGEs. XAGE-1 and XAGE-2 are expressed in Ewing's sarcoma, rhabdomyosarcoma, a breast cancer, and a germ cell tumor.

It is believed that the protein of SEQ ID NO:268 is a splicing variant of XAGE-1, a CT antigen overexpressed in Ewing sarcoma.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:268, fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition, such as those listed above, associated with over or under expression of the protein of SEQ ID NO:268. In such embodiments, the protein of SEQ ID NO:268, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activity of the protein of SEQ ID NO:268. The protein of SEQ ID NO:268 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:268 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:268 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:268 or a cell or preparation containing the protein of SEQ ID NO:268 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:268 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:268 may be identified by contacting the protein of SEQ ID NO:268 or a cell or preparation containing the protein of SEQ ID NO:268 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify tissues, preferably testis and lungs, or to distinguish between two or more possible sources of a tissue sample on the basis of the

level of the protein of SEQ ID NO:268 in the sample. For example, the protein of SEQ ID NO:268 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue

5 that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from testis or lungs or tissues other than testis or lungs to determine whether the test

10 sample is from testis or lungs. Alternatively, the level of the protein of SEQ ID NO:268 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:268 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic

15 acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from testis or lungs or tissues other than testis or lungs to determine whether the test sample is from testis or lungs.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:268,

20 including Ewing sarcoma cells, rhabdomyosarcoma cells, breast cancer cells and germ cell tumor cells using methods known to those skilled in the art. For example, an antibody against the protein of SEQ ID NO:268 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:268 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is

25 washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:268 or a fragment thereof thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:268. In some embodiments, the protein of SEQ ID NO:268 or fragments

30 thereof may be used to diagnose Ewing sarcoma, rhabdomyosarcoma, breast cancer or germ cell tumors. In such techniques, the level of the protein of SEQ ID NO:268 in an ill individual is measured using techniques such as those described herein. The level of the protein of SEQ ID NO:268 in the ill individual is compared to the level in normal individuals. An elevated level or decreased level of the protein of SEQ ID NO:268 relative to normal individuals suggests that the ill

35 individual is suffering from a defect in intercellular communication or secretion.

Another embodiment of the invention relates to compositions and methods using the protein of SEQ ID NO:268 or a fragment thereof as possible targets for vaccine-based therapies of cancer,

including Ewing sarcoma, rhabdomyosarcoma, breast cancer or germ cell tumors. In such embodiments, an antibody against the protein of SEQ ID NO:268 or a fragment thereof is administered to an individual suffering from cancer in an amount sufficient to ameliorate or eliminate the cancer.

5 Protein of SEQ ID NO:399 (internal designation (160-40-1-0-H4-CS))

The protein of SEQ ID NO:399 is encoded by the cDNA of SEQ ID NO:158. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:399 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 160-40-1-0-H4-CS. In addition, it will be appreciated that all characteristics and
 10 uses of the nucleic acid of SEQ ID NO:158 described throughout the present application also pertain to the human cDNA of clone 160-40-1-0-H4-CS. The protein of the invention is found to be expressed in testis and lungs. It is over represented in fetal brain.

The protein of SEQ ID NO:399 encoded by the cDNA of SEQ ID NO:158 is homologous to proteins of the Phosphatic Acid Phosphatase type 2 (PAP2) superfamily (Stukey J. and Carman
 15 G.M., Protein Sci 1997;6 :469-472, the disclosure of which is incorporated herein by reference in its entirety). Three variants of human PAP, i.e. PAP-alpha 2 (W79285) and its alternatively spliced form PAP-alpha 1 (W79284), PAP-beta (W79286) and PAP-gamma (W79287) have been identified. The protein of SEQ ID NO:399 displays a pfam characteristic domain of the PAP2 superfamily from positions 19 to 175. Accordingly, one embodiment of the present invention is a
 20 polypeptide comprising amino acid residues 19 to 175 of SEQ ID NO:399. Four membrane spanning domains are predicted from amino acid ositions 17 to, 47 to 67, 108 to 128, and 141 to 161. Accordingly, another embodiment of the present invention is a polypeptide comprising one or more of the foregoing membrane spanning domains.

Phosphatidic acid phosphatase (PAP) (also referred to as phosphatidate phosphohydrolase)
 25 is known to be an important enzyme for glycerolipid biosynthesis. In particular, PAP catalyzes the conversion of phosphatidic acid (PA) into diacylglycerol (DAG). PA and DAG are lipids involved in signal transduction and in structural membrane-lipid biosynthesis in cells, thus they represent an important regulatory point in eukariotic phospholipid metabolism. DAG is a well-studied lipid second messenger which is essential for the activation of protein kinase C (Kent; Anal. Rev.
 30 Biochem. ; 64 : 315-343;1995; whereas PA itself is also a lipid messenger implicated in various signaling pathways such as NADPH oxidase activation and calcium mobilization (English; Cell Signal.; 8:341-347 ;1996, the disclosure of which is incorporated herein by reference in its entirety). The regulation of PAP activity can therefore affect the balance of divergent signaling processes that the cell receives in terms of PA and DAG (Brindley et al.; Chem.Phys. Lipids 80:45-57 ; 1996, the
 35 disclosure of which is incorporated herein by reference in its entirety).

PAP exists in at least two isoforms, one of which (PAP1) is presumed to be cytosolic and membrane associated and the other (PAP2) to be an integral membrane protein (Leung D.W., Tompkins C.K., White T. ; DNA Cell Biol.17 : 377-385 (1998)). The protein of the invention has 180 amino-acids and four predicted membrane-spanning segments, so is presumed to be an integral
5 membrane protein.

The protein of SEQ ID NO:399 is encoded by a cDNA that has homology to many forms of alternative splicing of PAP2 genes. For example, the protein of SEQ ID NO:399 has 29% homology with human phosphatidic acid phosphohydrolase type-2C protein. The protein of SEQ ID NO:399 also has 40% homology with human phosphatidic acid phosphatase 2B protein. In
10 addition, the protein of SEQ ID NO:399 has 33% homology with human type 2 phosphatidic acid phosphatase alpha-2 protein. PAP2-alpha2 is one of the two isoforms with PAP2-alpha1, presumed to be alternative splice variants from a single gene.

Northern analysis has shown that PAP2-alpha mRNA expression was suppressed in several tumor tissues, indicating that PAP-2 may act as a tumor suppressor. The relationship of PAP and
15 tumor suppression is further evidenced in findings that PAP activity is lower in fibroblast cell lines transformed with either the *ras* or *fps* oncogene than in the parental rat1 cell line (Brindley et al ; Chem. Phys. Lipids 80 : 45-57 ;1996, the disclosure of which is incorporated herein by reference in its entirety). As discussed above, a decrease in PAP activity in transformed cells correlates with a concomitant increase in PA concentration. Moreover, elevated PAP activity and lower levels of PA
20 have been observed in contact-inhibited fibroblasts relative to proliferating and transformed fibroblasts (Brindley et al ; Chem. Phys. Lipids 80: 45-57;1996, the disclosure of which is incorporated herein by reference in its entirety). Therefore, the protein of SEQ ID NO:399 or fragments thereof may be used to decrease cell division and as such can provide a useful tool in treating cancer. Subsequent analysis of colon tumor tissue derived from four donors confirmed
25 lower expression of PAP2-alpha than in matching normal colon tissue. Considering these data and previous demonstrations that certain transformed cell lines have lower PAP activity, human PAP cDNAs may be used for gene therapy for certain tumors (Leung D.W., Tompkins C.K., White T. ; DNA Cell Biol.17 : 377-385 (1998), the disclosure of which is incorporated herein by reference in its entirety). Accordingly, one embodiment of the present invention is the use of the protein of
30 SEQ ID NO:399 or a fragment thereof as a tumor suppressor. For example, a nucleic acid expressing the protein of SEQ ID NO:399 or a fragment thereof may be introduced into an individual suffering from cancer in order to ameliorate or eliminate the cancer. In fact, nucleic acids encoding human phosphatidic acid phosphatases have been used to regulate levels of lipid cellular mediators and in gene therapy of e.g. cancer (PCT publication WO98/46730, the disclosure
35 of which is incorporated herein by reference in its entirety).

In another embodiment of the present invention, the protein of SEQ ID NO:399 or a fragment thereof can be used to control the balance of lipid mediators of cellular activation and

signal transduction. The protein of the invention has 33% homology with human phosphatidic acid phosphatase 2A protein. PAP2A is an integral membrane glycoprotein at the cell surface that plays an active role in the hydrolysis and uptake of lipids from the extracellular space (Roberts RZ, Morris AJ; Biochim Biophys Acta 2000 Aug 24;1487(1):33-49, the disclosure of which is
5 incorporated herein by reference in its entirety). Accordingly, the level or activity of the protein of SEQ ID NO:399 may be modulated to influence the rate or extent of hydrolysis and uptake of lipids from the extracellular space using methods such as those described herein.

In another embodiment of the present invention, the protein of SEQ ID NO:399 can be used to counterbalance the inflammatory response. PA has been implicated in cytokine induced
10 inflammatory responses (Bursten et al; Circ. Shok 44: 14-29, 1994; Abraham et al; J. Exp. Med. 181: 569-575, 1995; Rice et al; PNAS 91: 3857-3861, 1994; Leung et al; PNAS 92: 4813-4817, 1995, the disclosures of which are incorporated herein by reference in their entireties) and the modulation of numerous protein kinases involved in signal transduction (English et al ; Chem. Phys. Lipids 80: 117-132, 1996, the disclosure of which is incorporated herein by reference in its
15 entirety). In addition, a nucleic acid encoding the protein of SEQ ID NO:399 or a fragment thereof may be used to counterbalance the inflammatory response from cytokine stimulation through degradation of excess amount of PA in cells or to treat or ameliorate inflammatory diseases.

The gene encoding the protein of SEQ ID NO:399 or a fragment thereof can also be used in gene therapy for the treatment of obesity associated with diabetes. PAP activity is decreased in the
20 livers and hearts of the grossly obese and insulin resistant JCR:LA corpulent rat compared to the control lean phenotype (Brindley et al ; Chem. Phys. Lipids 80 : 45-57 ;1996, the disclosure of which is incorporated herein by reference in its entirety). The protein of the invention therefore can provide an important tool for the treatment of obesity associated with diabetes.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:399 ,
25 fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition, such as those listed above, in an individual. In such embodiments, the protein of SEQ ID NO:399 , or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:399, including
30 glycerolipid biosynthesis, conversion of phasphatidic acid into diacylglycerol, signal transduction, membrane-lipid biosynthesis, activation of protein kinase C, NADPH oxidase activation, calcium mobilization, cell division, production of diacylglycerol, monoacylglycerol, ceramide or sphingosine, modulation of the inflammatory response or dephosphorylation of a substrate such as lysophosphatidic acid, ceramide 1-phosphate, or sphingosine 1-phosphate, or treatment or
35 amelioration of obesity associated with diabetes. The protein of SEQ ID NO:399 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:399 or a fragment thereof may be administered to the individual.

Alternatively, an agent which increases the activity of the protein of SEQ ID NO:399 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:399 or a cell or preparation containing the protein of SEQ ID NO:399 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent
5 may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:399 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:399 may be identified by contacting the protein of SEQ ID NO:399 or a cell or preparation containing the protein of SEQ ID NO:399 with a test agent
10 and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify tissues, preferably brain, or
15 to distinguish between two or more possible sources of a tissue sample on the basis of the level of the protein of SEQ ID NO:399 in the sample. For example, the protein of SEQ ID NO:399 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that
20 has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochimistry. In such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from brain or tissues other than brain to determine whether the test sample is from brain.
25 Alternatively, the level of the protein of SEQ ID NO:399 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:399 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior
30 to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from brain or tissues other than brain to determine whether the test sample is from brain.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:399, including using methods known to those skilled in the art. For example, an antibody against the
35 protein of SEQ ID NO:399 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:399 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The

support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:399 or a fragment thereof thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:399. In some embodiments, the protein of SEQ ID NO:399 or fragments thereof may be used to diagnose cancer. In such techniques, the level of the protein of SEQ ID NO:399 in an ill individual is measured using techniques such as those described herein. The level of the protein of SEQ ID NO:399 in the ill individual is compared to the level in normal individuals. An elevated level or decreased level of the protein of SEQ ID NO:399 relative to normal individuals suggests that the ill individual may suffer from cancer or be predisposed to getting cancer in the future.

In another embodiment, the present invention relates to methods of preparing a PAP protein of SEQ ID NO:399 comprising the steps of (i) transforming a host cell with an expression vector comprising a polynucleotide encoding SEQ ID NO:399, (ii) culturing the transformed host cells which express the protein and (iii) isolating the protein. The present invention also relates to a method of dephosphorylating a substrate comprising contacting the substrate with an effective amount of isolated protein of SEQ ID NO:399 or a fragment thereof such that the protein catalyzes the dephosphorylation of the substrate. It is further provided that this method occurs *in vitro*, and comprises a step of isolating the dephosphorylated substrate. Additionally, the method can occur *in vivo*, and is effected by the administration of the protein of the invention (or part of it) to a mammal in need thereof.

Protein of SEQ ID NOs:258 and 262 (internal designations 110-007-1-0-C7-CS, 116-055-1-0-A3-CS):

The protein of SEQ ID NO:258 is encoded by the cDNA of SEQ ID NO:17. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:258 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 110-007-1-0-C7-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:17 described throughout the present application also pertain to the human cDNA of clone 110-007-1-0-C7-CS. The protein of SEQ ID NO:258 shows homologies to two high affinity IgE receptor-like proteins (IGER) with GENESEQP accession numbers W96745 and W41056, the disclosures of which are incorporated herein by reference in their entireties. The protein of SEQ ID NO:258 is expressed in liver and testis. The protein of SEQ ID NO:262, encoded by SEQ ID NO:21, is a variant of the protein of SEQ ID NO:258 and shares all the potential uses and functions described herein. This protein and cDNA share all of the characteristics and uses of the clone, and product thereof, 116-055-1-0-A3-CS).

Like the two high affinity IgE receptor-like proteins, the protein of the invention contains four transmembrane spanning domains of 20 amino acids, between amino acids 53-73, 79-99, 121-141 and 158-178, respectively. The protein of SEQ ID NO:258 crosses the plasma membrane four times forming two small extracellular loops and has both the N- or C- terminals in the cytoplasm.

5 Moreover, the protein of the invention contains a signal peptide (cleavage site at position 21).

The predicted structure of the protein of SEQ ID NO:258 demonstrates the relationship of this protein to FcεRIβ and CDC20 antigen and provides evidence for a family of 4-transmembrane spanning proteins. The conservation of amino acids between all three proteins is highest in the four transmembrane domains. While greater divergence exists in the hydrophilic amino and carboxyl
10 termini, several amino acids within these regions are conserved such as the presence of 4 prolines in the amino terminus of all three proteins. In addition, two cysteine residues (position 147 and 156) are present in the second extracellular domain between TM3 and TM4. This suggests that inter- or intra-molecular di-sulfite bonds in this domain are present in all three proteins.

FcεRI, is part of a tetrameric receptor complex consisting of an α chain, a β chain and two γ
15 chains (Kinet et al. Proc Natl. Acad. Sci. USA, 15: 6483-6487 (1988), the disclosure of which is incorporated herein by reference in its entirety). Together, they mediate interaction with IgE-bound antigens leading to dramatic cellular responses, such as the massive degranulations of mast cells. The β subunit is a 4-transmembrane protein with both the amino and carboxyl termini residing in the cytoplasm.

20 Chromosome mapping localized cDNA of SEQ ID NO:17 to chromosome 11q12, the location of the CD20 gene. However, the murine FcεRIβ and Ly-44 (the murine equivalent of CD20) are both located in the same position in mouse in chromosome 19 (Teder, T.F. et al., J. Immunol. 141:4388-4394 (1988), Clark E.A. and Lane, J.L. Annu. Rev. Immunol. 9:97-127 (1991), the disclosures of which are incorporated herein by reference in their entireties). Therefore, the
25 three genes are believed to have been originated and evolved from the same locus, further supporting the proposition that they are members of the same family of related proteins.

On the basis of the foregoing information, it is believed that the protein of SEQ ID NO:258 is a high affinity immunoglobulin E receptor-like protein.

Atopic diseases, which include allergy, asthma, atopic dermatitis (or eczema) and allergic
30 rhinitis are generally defined as a disorder of Immunoglobulin E (IgE) responses to common antigens, such as pollen or house dust mites. It is frequently detected by either elevated total serum IgE levels, antigen specific IgE response or positive skin tests to common allergens. In principle, atopy can result from dysregulation of any part of the pathway which begins with antigen exposure and IgE response to the interaction of IgE with its receptor on mast cell, the high affinity Fc
35 receptor FcεRI, and the subsequent cellular activation mediated by that ligand-receptor engagement (Ravetch, Nature Genetics, 7: 117-118 (1994), the disclosure of which is incorporated herein by reference in its entirety).

Accordingly, the protein of SEQ ID NO:258 or fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity may administered to an individual in whom it is desired to increase or decrease the activity of the protein of SEQ ID NO:258. In particular, the protein of SEQ ID NO:258 or fragment thereof may be administered to an individual in whom it is desired to regulate the extent of the IgE response. In such methods, the protein of SEQ ID NO:258 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:258 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:258 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:258 or a cell or preparation containing the protein of SEQ ID NO:258 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

The protein of SEQ ID NO:258 or fragments thereof may also be used to identify genes or polypeptides that may play a rôle in IgE responses or atopic disease. In particular, binding partners for the protein of SEQ ID NO:258 or the genes encoding such binding partners may be identified using a variety of techniques familiar to those skilled in the art, including the techniques described herein.

The protein of SEQ ID NO:258 or the polynucleotide encoding the protein of SEQ ID NO:258 may also be used to diagnose hereditary atopy. In particular, the level of the protein of SEQ ID NO:258 may be determined in a test individual using methods such as those described herein and compared to the levels of normal individuals and individuals suffering from hereditary atopy to determine whether the test individual is suffering from or at risk of suffering hereditary atopy. Alternatively, a nucleic acid sample may be obtained from a test individual and analyzed to determine whether it contains a level of RNA encoding the protein of SEQ ID NO:258 which is associated with hereditary atopy or a mutation in the gene encoding the protein of SEQ ID NO:258 which is associated with hereditary atopy. For example, a nucleic acid sample from the test individual may be contacted with a nucleic acid probe comprising the nucleic acid encoding the protein of SEQ ID NO:258 or a fragment thereof to determine the RNA level or whether the individual has a mutation associated with hereditary atopy. The probe may be either DNA, including cDNA or genomic DNA, or the probe may be RNA. Any of the methods familiar to those skilled in the art may be used in these diagnostic methods, including the methods described herein. For example, the presence of a mutation associated with hereditary atopy can be determined using methods generally known in the art, such as but not limited to PCR, sequencing or mini sequencing as described in the method of Yamamoto et al. (Biochem. Biophys. Res. Comm., 182:507 (1992), the disclosure of which is incorporated by reference herein in its entirety).

The protein of SEQ ID NO:258 can also be used to characterize the induction of expression of FcεRI and the particular function of FcεRIβ. As such, the protein of the invention can be useful in, for example, the design of drugs that block or inhibit induction or activity of FcεRI, thereby treating atopic diseases. In particular, test agents which block or inhibit induction or activity may
5 be identified using the methods described herein.

In an other embodiment, the protein of SEQ ID NO:258 can be employed in the preparation of antibodies, such as monoclonal antibodies, according to methods known in the art, including those described herein. The antibodies can be used to block or mimic ligand binding to the receptor comprising the protein of the invention or other receptors, such as but not limited to FcεRI. The
10 antibodies can also be used to isolate the protein of SEQ ID NO:258 or cells which express the protein of SEQ ID NO:258 using methods such as those described herein. For example, the antibodies may be used to measure the presence of cells containing the protein of SEQ ID NO:258 (including but not limited to hematopoietic cells) in a sample. For example, the method comprises contacting the sample with the antibody under conditions sufficient for the antibody to bind to the
15 protein of SEQ ID NO:258 and detecting the presence of bound antibody using methods known in the art, including those described herein.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify tissues, preferably liver and testis, or to distinguish between two or more possible sources of a tissue sample on the basis of the
20 level of the protein of SEQ ID NO:258 in the sample. For example, the protein of SEQ ID NO:258 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue
25 cross-section using immunochemistry. In such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from liver or testis or tissues other than liver or testis to determine whether the test sample is from liver or testis. Alternatively, the level of the protein of SEQ ID NO:258 in a test
30 sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:258 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in
35 control cells from liver or testis or tissues other than liver or testis to determine whether the test sample is from liver or testis.

Protein of SEQ ID NO:279 (internal designation 160-58-3-0-H3-CS)

The protein of SEQ ID NO:279 is encoded by the cDNA of SEQ ID NO:38. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:279 described throughout the present application also pertain to the polypeptide encoded by a nucleic acid included in clone 160-58-3-0-H3-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:38 described throughout the present application also pertain to the nucleic acid included in clone 160-58-3-0-H3-CS.

The protein of SEQ ID NO:279 is encoded by a nucleic acid of 1330 nucleotides with an ORF between nt 198 to 998 yielding a 267 amino acid protein. The protein is a polymorphic variant of the sequence (SP:P01210) for proenkephalin A precursor (contains Met- and Leu- enkephalins). It has a signal peptide spanning 24 amino acid and 2 signature motifs for vertebrate endogenous opioid neuropeptides and endogenous opioid neuropeptide precursors. PSORT gives a predicted extracellular localization, including the cell wall (66.7%). The protein of SEQ ID NO:279 is primarily distributed the fetal brain, although expression in other tissues has also been shown (see below). The polymorphic variation is found at amino acid position 75 (E→D, a conservative amino acid change). After signal peptide cleavage (amino acid 47 to 267; 220 amino acid), the protein still contains the polymorphic variation, which is now at amino acid position 29. This does not change any of the sequence of the different enkephalins that result after cleavage of this precursor protein. In addition, the polymorphism is 25 amino acids away from the first cleavage site on the amino terminal side. This is unlikely to change the secondary structure of the actual cleavage site.

PCT publication WO9606863-A1, the disclosure of which is incorporated herein by reference in its entirety, discloses a protein having high homology with the protein of SEQ ID NO:279. Accordingly, the protein of SEQ ID NO:279 is believed to be an enkephalin. Met- and Leu- enkephalins compete with and mimic the effects of opiate drugs. These two pentapeptides with potent opiate agonist activity in bioassay systems were originally identified by Hughes et al (Nature, 258, 577-580, 1975). The natural ligands for opiate receptors, which differ only in their COOH terminal amino acid, were named Met- and Leu-enkephalin to reflect their origin from the brain. Peptides containing these sequences are termed opiate or opioid peptides. Enkephalins are widely distributed throughout the central nervous system in enkephalinergic neuronal networks, and also exist in the peripheral nervous system, for example in autonomic ganglia. Data, largely circumstantial, suggest wide-ranging involvement of endogenous opioids for example in the modulation of pain perception, in mood and behaviour, learning and memory, responses to stress, diverse neuroendocrine functions, immune regulation and cardiovascular and respiratory function.

Met-enkephalin enhances the immune reaction in patients with cancer or AIDS. It can bind opioid receptors present in peripheral inflamed tissues to mediate an analgesic effect.

After exogenous administration of the different enkephalins, several immunologic functions are affected, including antibody production, NK cell activity against tumors and viral infections,

macrophage and polymorphonuclear leukocyte functions, graft rejections, and mitogen-stimulated lymphocyte proliferation. The effects can be bi-directional, where low concentrations enhance, and high concentrations inhibit the same immune function. Thus, enkephalins are modulators of immune reactions.

5 These opioid neuropeptides are released by post-translational proteolytic processing of precursor proteins. These multivalent precursor proteins (polyprotein) consist of a signal sequence followed by a conserved region of about 50 residues, a variable length region and the sequence of the various neuropeptides. The preproenkephalin A (gene PENK) is processed to produce the following peptides which include Met-enkephalin (6 copies, 2 of which are extended) and Leu-
10 enkephalin:

Signal peptide 1-24

Peptide 100-104 Met-enkephalin 1

Peptide 107-111 Met-enkephalin 2

Peptide 136-140 Met-enkephalin 3

15 Peptide 186-193 Met-enkephalin-arg-gly-leu

Peptide 210-214 Met-enkephalin 4

Peptide 230-234 Leu-enkephalin

Peptide 261-267 Met-enkephalin-arg-phe

 The conserved region in the N-termini of these precursors contains six cysteines that are
20 probably involved in disulfide bonds. This region could also be important for the processing of the neuropeptides.

 The precursor protein does have the potential to be differentially cleaved into multiple extended enkephalin and non-enkephalin-containing peptides, the functions of which are largely unknown; however, in some cases it has been shown that extended enkephalin-containing peptides
25 have enhanced opiate activity. Another peptide, enkelytin, is produced that exhibits anti-bacterial activity (see below).

 There is a growing body of evidence that proenkephalin exists largely independently of free enkephalin peptides in a number of tissues and cell types including astrocytes (Melner et al, EMBO J, 9, 791-796, 1990; Spruce et al, EMBO J 9, 1787-1795, 1990, the disclosures of which are
30 incorporated herein by reference in their entirety), and is released from these cells in an unprocessed form (Batter et al, Brain Res. 563, 28-32, 1991, the disclosure of which is incorporated herein by reference in its entirety). There is evidence in some cases that processing enzymes are co-released along with the unprocessed precursor which suggests that extracellular cleavage may occur (Vilijn et al, J. Neurochem. 53, 1487-1493, 1989). Even if biological activity is signalled through
35 binding of the small peptide products to cell surface receptors, the regulation of this activity may be mediated through the precursor, and it is also possible that the unprocessed precursor has an additional intracellular role of its own.

This protein was originally described to be present in various brain regions, most notably in the striatum as well as in neuroendocrine tissues, the pituitary and adrenal gland. It is also expressed in a variety of immune cells, including ConA-stimulated CD4 T lymphocytes, CD4 thymocytes, B lymphocytes, as well as T cell lines, macrophages and mast cells. Expression has
5 been reported in the reproductive system, heart and many developing tissues during gestation and early postnatal period. Because of this, it has been postulated that these peptides play a role in cell or tissue growth and differentiation. For example, endogenous enkephalins induced in thymocytes modulate their own expression and function to inhibit the proliferation of activated thymocytes.

Enkephalin peptides are abundant in adrenal medulla and can be released by
10 neurotransmitters specific for that tissue. Enkephalins have also been found to be abundant in human pheochromocytoma, a tumour derived from the adrenal medulla. The RNA from this tumour contains a high level of enkephalin mRNA sequences as demonstrated by cell-free translation studies.

Enkephalins function as opiate receptors are classified as delta, kappa and mu. A study by
15 Lord et al (Nature, 267, 495-499, 1977) compared the activity of morphine and enkephalins in bioassay systems, and found that enkephalins bound predominantly to delta receptors. Subsequent studies have revealed homology of these receptors to other receptor families, including the immunoglobulin superfamily member OBCAM (Schofield et al, EMBO J 8, 489-495, 1989, the disclosure of which is incorporated herein by reference in its entirety) and somatostatin receptors
20 (PCT publication WO96/06863, the disclosure of which is incorporated herein by reference in its entirety). This would explain the reported opioid binding properties of the former. Because of the latter's homology to opiate receptors, it would also be expected to bind opioid receptor ligands. The recognition of opioid peptides by other non-opiate related receptors implies that these peptides may exert other as yet unknown functions.

25 Enkephalins are also involved in apoptosis. Apoptosis is the morphologically distinct process of controlled cell death which balances the process of cell production by mitosis. A molecular connection between control of cell production and cell elimination has now been established, including the roles of c-myc and p53 in the pathways mediating apoptotic cell death. It has been proposed that all mammalian cells may be programmed to die by default in the absence of
30 continuous signalling from neighboring cells. However, the acquisition of a survival advantage which prevents a single cell from activating its suicide program in response to levels of genetic damage associated with common environmental insults could theoretically be an initiating event in oncogenesis since it would favor the persistence of potentially tumorigenic mutations. Alternatively, inappropriate activation of survival pathways might lead to overriding the intrinsic
35 death program and promote tumorigenesis at early and late stages. A particularly potent oncogenic pathway would be one which both promoted and tolerated genetic damage and helped a cell overcome its need for extracellular survival signals. Approximately 50% of human tumors possess

normal p53 function. Thus, additional pathways or molecules which inappropriately repress apoptosis in human tumours remain to be identified. Opioid-like molecules could be involved in such a pathway.

There are published reports that pathways which include opioid-like molecules participate in regulating the equilibrium between cell death and survival. For example, morphine inhibits cell survival in the developing cerebellum (Hauser et al, Exp. Neurol, 130, 95-105, 1994, the disclosure of which is incorporated herein by reference in its entirety) and induces apoptosis in thymocytes (Fuchs and Pruett, J. Pharmacol. Exp. Ther. 266, 417-423, 1993, the disclosure of which is incorporated herein by reference in its entirety).

In a series of experiments (PCT publication WO 96/06863), it has been found that proenkephalin and/or its proteolytic products act as extracellular and/or cell surface membrane bound factors which modulate cell survival in transformed cells a) upon deprivation of exogenous survival factors, and b) following genotoxic injury and/or stress when exogenous survival factors are non-limiting. The receptor(s) to which these factor(s) bind, which are most likely to exist on the cell surface are related, or possibly identical, to one or more members of the opioid receptor family.

Opioid-like receptor types or subtypes can mediate survival or death; receptor (s) which mediate death appear to be coupled to those which mediate survival. Natural ligands for these receptors are likely to be products of the opioid precursor genes, although natural ligands could include cytokines which mimic their effect. Tumour cells are more sensitive to antagonism of opioid-like receptor-mediated survival, and to stimulation of opioid-like receptor-mediated death, than non-transformed cells. The induction of cell cycle arrest enhances the sensitivity of tumour cells to these manipulations. (Enhanced sensitivity of tumour cells to these manipulations is induced by their synchronisation within the cell cycle.

Cytoplasmic proenkephalin and/or its proteolytic products act as general repressors of apoptosis. Agents which, if coupled to appropriate internalisation agents, would antagonise cytoplasmic proenkephalin would therefore be of use in the induction of apoptosis in non-transformed as well as transformed cells, particularly in combination with sublethal doses of known apoptosis-inducing agents.

The repression of apoptosis mediated through cytoplasmic proenkephalin is activated at high cell density predominantly by nondiffusable factors. Inhibition of proenkephalin or its products as described above would therefore be potentiated if agents were used in combination for example with neutralising antibodies to integrins (such as the antibody 23C6- Bates et al., J. Cell Biol. 125 403-415, 1994) to reduce exogenous survival signaling and simulate low density.

Proenkephalin targeted to the cell nucleus induces apoptotic death, which is inhibited by the overexpression of large T antigen and is at least partly mediated through p53. Tumors which retain wild-type p53 function are therefore a particular target for apoptosis induction by agents which

increase the levels of proenkephalin, or its derivatives, within the nucleus or which mimic the function of nuclear proenkephalin or its derivatives.

Accordingly, the protein of SEQ ID NO:279, fragments thereof, or nucleic acids encoding the protein of SEQ ID NO:279 may be used to modulate a biochemical pathway in which products of opioid peptide precursor genes participate. In some embodiments, antibodies or other agents which reduce the level or activity of the protein of SEQ ID NO:279 or fragments thereof may be used to induce apoptosis in cells. The agents preferably neutralize the protein of SEQ ID NO:279 or its proteolytic derivatives, increase the level of, activate or mimic nuclear proenkephalin, or act as an antagonist to receptors related or identical to the delta and kappa opioid receptors. In some embodiments, the agent may be a neutralizing monoclonal antibody against the protein of SEQ ID NO:279 or a fragment thereof. The agent may also be a fragment or allelic form of one of these antibodies. A cytoplasmic anchor, or a nuclear localization signal may also be included in the agent. In some embodiments, the agent is able to modulate a biochemical pathway in a cell in which products of opioid peptide precursor genes participate in order to induce apoptosis. The agents can be used for the treatment of cancer or for inducing apoptosis in lens cells following a cataract operation. In some embodiments, the agents promote apoptosis of proliferating cells with less, or no, effect on normal mature cell types. The agents may be administered in combination with a genotoxic or cell cycle arrest agent. Alternatively, the agent may be complexed with a chemotherapeutic, irradiation or cell cycle arrest (synchronization agent).

Accordingly, the invention provides a means of inducing apoptosis in cells which comprises modifying a biological pathway of a cell in which a product of an opioid precursor gene participates in such a way that apoptosis is induced. Modification of the pathway is suitably effected by administration of an appropriate agent. In particular, the present invention provides an agent for use in inducing apoptosis in cells, said agent comprising an agent able to neutralise proenkephalin or its proteolytic derivatives; an agent which increases the level of nuclear proenkephalin and/or its derivatives, or which activates or mimics them an agent which acts as an antagonist at receptor(s) related or identical to the delta opioid receptor, or an agent which acts as an agonist at receptor(s) related or identical to the kappa opioid receptor.

A subset of such agents are agents able to neutralise proenkephalin or its proteolytic derivatives, or an agent which acts as an antagonist at receptor(s) related or identical to the delta opioid receptor, or an agent which acts as an agonist at receptor(s) related or identical to the kappa opioid receptor.

In some embodiments, the agent may be administered to the cell surface whereupon the survival effects of extracellular and/or cell surface membrane bound proenkephalin or its proteolytic derivatives is neutralised causing the cell to become apoptotic. Alternatively, an agent able to neutralise proenkephalin or its proteolytic derivatives may be coupled to an internalisation peptide and a cytoplasmic anchor. Such an assembly will remain in the cytoplasm of the cell, antagonising

cytoplasmic proenkephalin and/or its proteolytic products and thus neutralising the apoptosis repressor effect of these molecules.

Enkephalins also have anti-bacterial activity. During processing of the proenkephalin-A, the maturation in the adrenal medullary chromaffin cell starts with the removal of the carboxy-terminal end (proenkephalin-A-derived peptide or PEAP₂₀₉₋₂₃₉) (Y. Goumon, K. Lugardon, B. Kieffer et al. J. Biol. Chem. 273:29847-29856, 1998, the disclosure of which is incorporated herein by reference in its entirety). The peptide enkelytin was identified as corresponding to bisphosphorylated PEAP₂₀₉₋₂₃₇, and possesses antibacterial activity including *Staphylococcus aureus* and other gram-positive bacteria such as *Micrococcus luteus* and *Bacillus megaterium* (0.2-0.4 μ M range). There is no ability to affect gram-negative bacteria (E. coli strain D22, D31, 663 and T13773) growth, nor is there any hemolytic activity. The activity of this peptide is specific – shorter versions of the peptide (209-220, 224-237, 230-237, 233-237) or non-phosphorylated PEAP₂₀₉₋₂₃₉ exhibited little to no bacterial growth inhibiting activity.

Bovine periartthritis abscess fluid contains different forms of PEAP (72-237/239; 80-237/239) as identified by immunoreactivity and confirmed by sequence analysis. These peptides have activity against *M. luteus*, but are less active than enkelytin (5 versus 0.2 μ M). These PEAP constitute a pool of precursors which have to be processed, during infection, to provide active enkelytin. Presence of a PEAP at a molecular mass corresponding to that of PEAP₂₀₉₋₂₃₇ was detected as well. PEAPs (PEAP₂₀₂₋₂₃₈ and PEAP₂₀₆₋₂₃₇) have also been detected in wound fluids, including bovine post-caesarean abscess in the subcutaneous lining, and an abscess induced by subcutaneous injection of complete Freund's adjuvant. Therefore, these peptides are present in wound fluids along with other known antibacterial peptides (defensins, bactericins). The concentrations were in a range similar to that found to be active *in vitro* (0.5-1 μ M). The PEAPs have also been detected in secretions from human polymorphonuclear neutrophils.

The PEAP₂₀₉₋₂₃₀ and enkelytin are secreted from cultured chromaffin cells following stimulation. This suggests that these two peptides are co-released with catecholamines in stress situations and may therefore play an important role in defense mechanisms.

Co-release of met-enkephalin and enkelytin would represent a unified neuroimmune protective response to stress situations that may be accompanied with infectious diseases. This would provide a highly beneficial survival strategy at the very beginning of proinflammatory processes. This protein would therefore play an important role in host defense against microbial infections, especially those involving gram positive bacteria. Due to their nonspecific activity on membranes, the antibacterial peptides possess cytotoxic activities and may not only play a role in antimicrobial defense, but also in inflammatory processes, possibly in wound repair.

The protein of SEQ ID NO:279, peptides derived by cleavage thereof or fragments thereof could be used as antibacterial agents in creams/ointments/solutions, presoaked bandages, or dermal-type patches for external applications. Alternatively, the protein of SEQ ID NO:279, peptides

derived by cleavage thereof, or fragments thereof may be used in injections (intravenously, subcutaneously or intra-peritoneally). This is useful for wound repair, burn healing, post-operative recovery management.

Alternatively, the protein of SEQ ID NO:279, peptides derived by cleavage thereof, or
5 fragments thereof, may be incorporated into disinfectant solutions used for cleaning surfaces such as in the the house (kitchen, bathroom) or in the office (desktops, phones, computer keyboards and mouse). Other applications are as additives in mouthwash or handi-popup wipes.

Altered levels of enkephalins may produce psychological disease. Konig et al (Nature, 383, 535-538, 1996, the disclosure of which is incorporated herein by reference in its entirety) used a
10 genetic approach to study the role of the mammalian opioid system. They disrupted the pre-proenkephalin gene using homologous recombination in embryonic stem cells to generate enkephalin-deficient mice. Mutant enk -/- animals are healthy, fertile, and care for their offspring, but display significant behavioral abnormalities. Mice with the enk -/- genotype are more anxious and males display increased offensive aggressiveness. Mutant animals show marked differences
15 from controls in supraspinal, but not in spinal, responses to painful stimuli. These enk -/- mice do however exhibit normal stress-induced analgesia. Therefore, enkephalins modulate responses to painful stimuli. Thus, genetic factors may contribute significantly to the experience of pain. This study clearly indicates the importance of enkephalins in pain perception, anxiety and aggressiveness.

20 Interestingly, the PENK gene is localized on 8q23-q24, the same locus on which are found genes related to epilepsy and spastic paraplegia, disorders related to brain dysfunction.

Accordingly, the protein of SEQ ID NO:279 or fragments thereof may be used for the treatment of psychological disorders, especially those involving distortion in the perception of pain, aggressiveness, or anxiety. This would include drug addiction, different types of phobias, panic
25 attacks, schizophrenia, bi-polar, anorexia nervosa, chronic pain disorders, post-traumatic events. post-operative pain management.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:279, fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200 consecutive amino acids thereof, or fragments having a desired biological activity to treat or
30 ameliorate a condition in an individual. For example, the condition may be cancer, a condition resulting from increased or decreased cellular proliferation, bacterial infection, conditions resulting from abnormal immune responses, psychological disease or any of the conditions listed above. In such embodiments, the protein of SEQ ID NO:279, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ
35 ID NO:279. The protein of SEQ ID NO:279 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:279 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the

activity of the protein of SEQ ID NO:279 may be administered to the individual. Such agents may be identified by contacting the protein of SEQ ID NO:279 or a cell or preparation containing the protein of SEQ ID NO:279 with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:279 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:279 may be identified by contacting the protein of SEQ ID NO:279 or a cell or preparation containing the protein of SEQ ID NO:279 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify the source of a sample as, for example, fetal brain, or to distinguish between two or more possible sources of a sample on the basis of the level of the protein of SEQ ID NO:279 in the sample. For example, the protein of SEQ ID NO:279 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from fetal brain or tissues other than fetal brain to determine whether the test sample is from fetal brain. Alternatively, the level of the protein of SEQ ID NO:279 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:279 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from fetal brain or tissues other than fetal brain to determine whether the test sample is from fetal brain.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:279, including using methods known to those skilled in the art. For example, an antibody against the protein of SEQ ID NO:279 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:279 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The

support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:279 or a fragment thereof thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:279. In such techniques, the level of the protein of SEQ ID NO:279 in an ill individual is measured using techniques such as those described herein. The level of the protein of SEQ ID NO:279 in the ill individual is compared to the level in normal individuals to determine whether the individual has a level of the protein of SEQ ID NO:279 which is associated with disease.

10 Protein of SEQ ID NO: 293 (internal designation 181-16-1-0-G7-CS)

The protein of SEQ ID NO: 293 has a high degree of homology with HSPC163 (Genbank accession number AF161512), the protein encoded by gene no: 93 (PCT/US99/17130) and the human cornichon protein TGAM77. SEQ ID NO: 293 is overexpressed in cancerous prostate, fetal brain and fetal kidney.

15 The gene HSPC163 is one of three hundred cDNAs obtained from CD34+ hematopoietic stem / progenitor cell (HSPC) library (obtained from umbilical cord blood and adult bone marrow). HSPC163 has also been identified in five hematopoietic cell lines: NB4 (granulocytic), HL60 (granulocytic), U937 (monocytic), K562 (erythro-megakaryocytic), and Jurkat (T lymphocytic). These cell lines represent the distinct lineages of hematopoietic cells.

20 The polypeptide of gene no: 93 has been determined to have two transmembrane domains and a short cytoplasmic tail. Based upon these characteristics, it is believed that the protein product of gene no: 93 shares structural similarity to type IIIa membrane proteins. This gene is expressed primarily in activated T-cells and to a lesser extent in endometrial tumor, T cell helper II cells, microvascular endothelial cells, Raji cells treated with cyclohexamide and umbilical vein endothelial cells. The expression pattern of gene no: 93, indicates a role in regulating the proliferation, survival, differentiation, and/or activation of hematopoietic cell lineages, including blood stem cells. The gene product appears to be involved in the regulation of cytokine production, antigen presentation, and other immune processes, suggesting a usefulness in boosting the immune system. The translation product of this gene has high homology to the human TGAM77 and mouse cornichon proteins.

TGAM77 was identified as a gene involved in early phase of T-cell activation in response to alloantigens. Twenty four hours after T-cell allostimulation, RNA expression of TGAM77 is significantly increased. TGAM77 has been designated as a T-cell growth associated molecule. TGAM77 is a human homolog of cornichon (cni) protein of the fruit fly *Drosophila*.

35 Cornichon was demonstrated to be involved in carefully orchestrated signaling events during *Drosophila* oogenesis establishing an asymmetric pattern in the oocyte as a prerequisite for

correct embryogenesis. Cornichon signaling functions in concert with two other proteins. The function of all three genes in an EGF-like signaling pathway appears to direct the formation of a correctly polarized microtubule cytoskeleton, which is thought to be the basis for the correct spatial localization of other signaling molecules essential for oocyte polarization, asymmetric movement
5 of the nucleus, and embryo differentiation.

The subject invention provides the amino acid sequence of SEQ ID NO: 293 and polynucleotide sequences encoding the amino acid sequence of SEQ ID NO: 293. In one embodiment, the polypeptides of SEQ ID NO: 293 are interchanged with the corresponding polypeptides encoded by the human cDNA of clone 181-16-1-0-G7-CS. Also included in the
10 invention are biologically active fragments of SEQ ID NO: 293 and polynucleotide sequences encoding these biologically active fragments. "Biologically active fragments" are defined as those peptide or polypeptide fragments of SEQ ID NO: 293 which have at least one of the biological functions of the full length protein (e.g., the ability to stimulate T-cell proliferation).

The invention also provides variants of SEQ ID NO: 293. These variants have at least
15 about 80%, more preferably at least about 90%, and most preferably at least about 95% amino acid sequence identity to the amino acid sequence of SEQ ID NO: 293. Variants according to the subject invention also have at least one functional or structural characteristic of SEQ ID NO: 293, such as the biological functions described above. The invention also provides biologically active fragments of the variant proteins. Unless otherwise indicated, the methods disclosed herein can be
20 practiced utilizing SEQ ID NO: 293 or variants thereof. Likewise, the methods of the subject invention can be practiced using biologically fragments of SEQ ID NO: 293, or variants of said biologically active fragments.

Because of the redundancy of the genetic code, a variety of different DNA sequences can encode SEQ ID NO: 293. It is well within the skill of a person trained in the art to create these
25 alternative DNA sequences which encode proteins having the same, or essentially the same, amino acid sequence. These variant DNA sequences are, thus, within the scope of the subject invention. As used herein, reference to "essentially the same" sequence refers to sequences that have amino acid substitutions, deletions, additions, or insertions that do not materially affect biological activity. Fragments retaining one or more characteristic biological activity of SEQ ID NO: 293 are also
30 included in this definition.

"Recombinant nucleotide variants" are alternate polynucleotides which encode a particular protein. They can be synthesized, for example, by making use of the "redundancy" in the genetic code. Various codon substitutions, such as the silent changes which produce specific restriction sites or codon usage-specific mutations, can be introduced to optimize cloning into a plasmid or
35 viral vector or expression in a particular prokaryotic or eukaryotic host system, respectively.

SEQ ID NO: 293 protein, and variants thereof, can be used to produce antibodies according to methods well known in the art. The antibodies can be monoclonal or polyclonal. Antibodies can

also be synthesized against fragments of SEQ ID NO: 293 as well as variants of SEQ ID NO: 293 according to known methods. The subject invention also provides antibodies which specifically bind to biologically active fragments of SEQ ID NO: 293 or biologically active fragments of SEQ ID NO: 293 variants.

5 The subject invention also provides for immunoassays which are used to screen for, monitor, or diagnose prostate cancer. Methods of screening for, diagnosing, identifying, or monitoring the course of prostate cancer are well known to those skilled in the art. In this aspect of the invention, immunoassays are provided which contact a biological sample (e.g., blood, serum, tissue, or biopsied tissue sample) with antibodies which specifically bind to SEQ ID NO: 293 ,
10 immunogenic fragments of SEQ ID NO: 293 , or biologically active fragments of SEQ ID NO: 293 . Immunocomplexes formed in the contacting step are then detected using an appropriately labeled detection reagent. The levels of SEQ ID NO: 293 expressed in the tested biological samples are compared to control/normal levels typically observed in the population.

 Alternatively, methods which screen for, monitor, or diagnose prostate cancer may be
15 practiced with SEQ ID NO: 293 , or fragments of SEQ ID NO: 293 , as well as nucleic acids encoding SEQ ID NO: 293 , or fragments of SEQ ID NO: 293 . In one embodiment, the polypeptide may be used as a standard/control immunoassays described above. In another embodiment, the nucleic acids encoding SEQ ID NO: 293 , or fragments of SEQ ID NO: 293 are used in hybridization assays, well known to the skilled artisan, to identify biological samples (e.g.,
20 blood, serum, tissue, or biopsied tissue sample) which contain SEQ ID NO: 293 . The levels of SEQ ID NO: 293 expressed in the tested biological samples are compared to control/normal levels typically observed in the population.

 In another embodiment, SEQ ID NO: 293 , and polynucleotide sequences encoding the amino acid sequence of SEQ ID NO: 293 can be used to identify or diagnose immune disorders
25 involving activated T-cells using standard hybridization assays.

 Another aspect of the invention provides methods of immunostimulating a mammal. In this aspect of the invention, SEQ ID NO: 293 , and/or polynucleotide sequences encoding the amino acid sequence of SEQ ID NO: 293 , are introduced into T-cells according to well known methods. T-cells are, then activated by stimulation with antigen to induce the immune system of the mammal.

30 In another embodiment, autologous T-cells are obtained from an individual. SEQ ID NO: 293 , biologically active fragments thereof, and/or polynucleotide sequences encoding the amino acid sequence, or biologically active fragments, of SEQ ID NO: 293 , are introduced into these autologous T-cells according to well known methods. The T-cells are expanded and reintroduced into the individual from which the T-cells were obtained. See, for example U.S. Patent Nos.
35 5,192,537 and 5,766,920 , hereby incorporated by reference in their entirety.

 In another embodiment of the subject invention, polynucleotides and polypeptides encoding SEQ ID NO: 293 , can be used to expand stem cells, committed progenitors of various

blood lineages, and in the differentiation and/or proliferation of various cell types. In this aspect of the invention, polynucleotides and polypeptides encoding SEQ ID NO: 293 are introduced into the cells and the cells cultured. These methods may be practiced according to methods well known to the routineer.

5 Protein of SEQ ID NO:316 (internal designation 188-45-1-0-D9-CS)

The protein of SEQ ID NO:316 is encoded by the cDNA of SEQ ID NO:75. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:316 described throughout the present application also pertain to the polypeptide encoded by a nucleic acid included in clone 188-45-1-0-D9-CS. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:75 described throughout the present application also pertain to the nucleic acid included in clone 188-45-1-0-D9-CS.

The protein of SEQ ID NO:316 is expressed in brain and contains three membrane-spanning segments located between amino acid positions 6 and 26, 73 and 93, or 139 and 159 and a signal peptide comprising the sequence FA AFCYMLSLVLC/AA. Accordingly, one embodiment of the present invention is a polypeptide comprising one or more of the membrane-spanning segments, and/or the signal peptide.

The protein of SEQ ID NO:316 is a member of the cornichon protein family. It has 48% identity with the *Drosophila melanogaster* cornichon protein as well as 67% identity with the Human Cornichon homolog TGAM77 (Genbank accession No. AF104398, the disclosure of which is incorporated herein by reference in its entirety), 67% identity with hCornichon, a bone marrow secreted protein (PCT publication WO/9933979, the disclosure of which is incorporated herein by reference in its entirety), 67% identity with a human secreted protein encoded by gene 24 (PCT publication WO/9910363, the disclosure of which is incorporated herein by reference in its entirety) and 67% identity with the protein product of the mouse *cnih* gene. However, this protein has higher homology, 81% identity, to the mouse cornichon-like protein (Genbank accession No. AB006191, the disclosure of which is incorporated herein by reference in its entirety), which is the product of the mouse *cnil* gene. Finally, the protein of SEQ ID NO:316 has a high level of identity with human secreted protein encoded by gene 95 (GSP:Y76218, PCT publication WO/9958660, the disclosure of which is incorporated herein by reference in its entirety) and is likely a polymorphic variant of gene 95. The high degree of sequence conservation between the members of this family indicates that they are under strong selective pressure and are likely involved in important cellular functions.

The *Drosophila cornichon (cni)* gene product is involved in signaling processes necessary for both anterior-posterior and dorsal-ventral pattern formation during *Drosophila* embryogenesis (Cell, 1995, 81:967-978). Mutations in *cornichon* prevent the formation of a correctly polarized microtubule cytoskeleton in the oocyte. *Cni* signaling functions in concert with two other proteins.

Gurken, which is a protein secreted from the oocyte containing a single epidermal growth factor (EGF) motif most similar in structure to vertebrate TGF α , is considered to be the ligand of the *Drosophila* epidermal growth factor receptor (DER) homolog torpedo, which is expressed by the follicular epithelium. The function of all three genes in an EGF-like signaling pathway appears to
5 direct the formation of a correctly polarized microtubule cytoskeleton, which is thought to be the basis for the correct spatial localization of other signaling molecules essential for oocyte polarization, asymmetric movement of the nucleus, and embryo differentiation. TGAM77, one of the human homologs of cornichon, is differently expressed in alloactivated T-cells (Bioch. Biophys. Acta 1999, 1449:203-210, the disclosure of which is incorporated herein by reference in its
10 entirety). Since there is a well-known involvement of the microtubule cytoskeleton in spatial polarization of signaling events in T-cell activation, it is thought that TGAM77 may function in a protein-tyrosine kinase pathway required for the vectorial localization of signaling molecules in T-cell activation.

The protein of SEQ ID NO:316 is found in brain tissue, and gene 95 (GSP:Y76218, PCT
15 publication WO/9958660, the disclosure of which is incorporated herein by reference) is expressed in infant brain tissue, endometrial tumor tissue and frontal cortex tissue. ESTs matching this gene are also found in lung tissue, germ cell tumors and skin melanomas. This is similar to the expression pattern of the murine *cnil* gene, which is found in 6.5-day whole embryos, 11.5-day limb bud, 13.5-day whole embryo, adult lung and brain (Dev. Genes Evol., 1999, 209:120-125, the
20 disclosure of which is incorporated herein by reference in its entirety).

Polynucleotides encoding the protein of SEQ ID NO:316 or fragments thereof and polypeptides comprising the protein of SEQ ID NO:316 or fragments thereof are useful as reagents for differential identification of the tissue(s) or cell type(s) present in a biological sample and for diagnosis of diseases and conditions which include, but are not limited to, endometrial tumor, and
25 neural and developmental diseases and/or disorders. Similarly, the protein of SEQ ID NO:316 or fragments thereof and antibodies directed to these polypeptides are useful in providing immunological probes for differential identification of the tissue(s) or cell type(s). For a number of disorders of the above tissues or cells, particularly of the neural and reproductive organs, expression of this gene at significantly higher or lower levels may be routinely detected in certain tissues or cell
30 types (e.g., neural, reproductive, cancerous and wounded tissues) or bodily fluids (e.g. lymph, serum, plasma, urine, amniotic fluid, synovial fluid and spinal fluid) or another tissue or cell sample taken from an individual having such a disorder, relative to the standard gene expression level, i.e., the expression level in healthy tissue or bodily fluid from an individual not having the disorder.

The tissue distribution in infant brain tissue and adult brain tissue, as well as the homology
35 to cornichon proteins, indicates that polynucleotides encoding the protein of SEQ ID NO:316 or fragments thereof and polypeptides comprising the protein of SEQ ID NO:316 or fragments thereof are useful for detecting and/or treating neural and developmental disorders. The tissue distribution

indicates that these polynucleotides and polypeptides are useful for the detection/treatment of neurodegenerative disease states and behavioural disorders such as Alzheimers Disease, Parkinsons Disease, Huntingtons Disease, Tourette Syndrome, schizophrenia, mania, dementia, paranoia, obsessive compulsive disorder, panic disorder, learning disabilities, ALS, Psychoses, autism, and
5 altered behaviors, including disorders in feeding, sleep platterns, balance, and perception. In addition, the gene or gene product may also play a role in treatment and/or detection of developmental disorders associated with the developing embyo, or sexually-linked disorders,

Elevated expression of the protein of SEQ ID NO:316 within the brain suggests that it may be involved in neuronal survival, synapse formation, conductance, neural differentiation, etc. Such
10 involmment may impact many processes, such as learing and cognition. Alternatively, the tissue distribution in endometiral tumor tissue, germ cell tumors and skin melanomas indicates that the translation product of this gene is useful for the detection and/or treatment of endometrial tumors and/or reproductive disorders, as well as tumors of other tissues where expression of this gene has been observed. Furthermore, the protein of SEQ ID NO:316 or fragments thereof may also be used
15 to determine biological activity, to raise antibodies, as a tissue marker, to isolate cognate ligands or receptors, to identify agents that modulate their interactions, in addition to its use as a nutritional supplement. The protein of SEQ ID NO:316 or fragments thereof, as well as, antibodies directed against the protein may be used as tumor marker and/or immunotherapy targets for the above listed tissues.

20 The gene encoding the protein of SEQ ID NO:316 is thought to reside on chromosome 11. Accordingly, polynucleotides encoding the protein of SEQ ID NO:316 or fragments thereof are useful as a marker in linkage analysis for chromosome 11.

Accordingly, the present invention includes the use of the protein of SEQ ID NO:316 , fragments comprising at least 5, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, or 200
25 consecutive amino acids thereof, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. For example, the condition may be an abnormality in development, a signaling pathway, microtubule construction, neuronal survival, synapse formation, conductance, neuarl differentiation, or it may be cancer or an abnormality in any of the functions listed above. In such embodiments, the protein of SEQ ID NO:316, or a fragment thereof, is
30 administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:316. The protein of SEQ ID NO:316 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:316 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:316 may be administered to the
35 individual. Such agents may be identified by contacting the protein of SEQ ID NO:316 or a cell or preparation containing the protein of SEQ ID NO:316 with a test agent and assaying whether the

test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide.

Alternatively, the activity of the protein of SEQ ID NO:316 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of the protein of SEQ ID NO:316 may be identified by contacting the protein of SEQ ID NO:316 or a cell or preparation containing the protein of SEQ ID NO:316 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

In one embodiment, the invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify the source of a sample as, for example, brain, or to distinguish between two or more possible sources of a sample on the basis of the level of the protein of SEQ ID NO:316 in the sample. For example, the protein of SEQ ID NO:316 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from brain or tissues other than brain to determine whether the test sample is from brain.

Alternatively, the level of the protein of SEQ ID NO:316 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:316 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from brain or tissues other than brain to determine whether the test sample is from brain.

In another embodiment, antibodies to the protein of the invention or part thereof may be used for detection, enrichment, or purification of cells expressing the protein of SEQ ID NO:316, including using methods known to those skilled in the art. For example, an antibody against the protein of SEQ ID NO:316 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:316 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the cells are released from the support by contacting the support with agents which cause the cells to dissociate from the antibody.

In another embodiment of the present invention, the protein of SEQ ID NO:316 or a fragment thereof may be used to diagnose disorders associated with altered expression of the protein of SEQ ID NO:316. In such techniques, the level of the protein of SEQ ID NO:316 in an ill individual is measured using techniques such as those described herein. The level of the protein of
5 SEQ ID NO:316 in the ill individual is compared to the level in normal individuals to determine whether the individual has a level of the protein of SEQ ID NO:316 which is associated with disease.

Protein of SEQ ID NO:255 (106-037-1-0-E9-CS.cor)

The protein of SEQ ID NO:255, encoded by the cDNA of SEQ ID NO:14, is strongly
10 expressed in the liver and testis and shows extensive homology to human lactate dehydrogenase-A protein (LDH-A or M chain) (Chung F.Z. et al., Biochem. J. 231:537-541(1985); SwissProt accession number P00338). The protein of SEQ ID NO:255 is also homologous to lactate dehydrogenase A from many vertebrates. The 381-amino-acid-long protein of SEQ ID NO:255 displays a Prosite motif corresponding to lactate dehydrogenase from positions 71 to 380. In
15 addition, the active site LGEHGDS, where H is the active site residue, is present in the protein of the invention (positions 239 to 245). The protein of the invention also contains an additional 50 N-terminal amino acids not found in other lactate dehydrogenase A proteins. This N-terminal extension contains a signal peptide (cleavage site at position 34 of the protein of invention) that may allow the export of the protein to the extracellular domain or define a particular subcellular
20 localization. Alternatively, the initiation start codon could be at position 26 or 50 of the protein of SEQ ID NO:255.

Lactate dehydrogenase (LDH) is an enzyme which dehydrogenates lactic acid into pyruvic acid in conjunction with the hydrogen acceptor NAD⁺, and which exists in a wide variety of animal tissues and microorganisms as an enzyme serving to produce lactic acid
25 from pyruvic acid in the glycolytic pathway (Abad-Zapatero C. et al. J. Mol. Biol. 198:445-467(1987)). It is known that in vertebrates there are three isozymes of LDH: the M form (LDH-A), found predominantly in muscle tissues; the H form (LDH-B), found in heart muscle, and the X form (LDH-C), found only in the spermatozoa of mammals and birds. In birds and crocodilian eye lenses, LDH-B serves as a structural protein and is known as
30 epsilon-crystallin (Hendriks W. et al. Proc. Natl. Acad. Sci. U.S.A. 85:7114-7118(1988)).

LDH has been used extensively in the field of clinical test reagents for a number of purposes. For example, it has been used as a coupling enzyme to determine the enzymatic activity of various amino-transferases, such as alanine aminotransferase (ALT), which is ultimately detected by UV spectrometry of the produced pyruvic acid. This use of LDH
35 has been widely adopted as a clinical test, because amino-transferases are enzymes which

show high activity in liver, heart, kidney, etc. and show remarkable increases in serum in association with various diseases. LDH has also been used as a coupling enzyme to help determine the level of substrates such as urea, as the enzyme promotes the conversion of such substances into pyruvic acid which can be detected by UV spectrometry.

5 Lactate dehydrogenase is also a widely used marker for heart disease and other conditions. For example, levels of LD-1 are elevated in the presence of myocardial infarction and in other conditions such as leukemia. Levels of lactate dehydrogenase start to increase 24 to 48 hours after occlusion of the coronary artery, peak in 3 to 6 days, and return to normal in 8 to 14 days. In addition, levels of LD-1 are elevated 10 to 12 hours
10 after the acute myocardial infarction, peak in 2 to 3 days, and return to normal in approximately 7 to 10 days. Thus, measurement of the level of lactate dehydrogenase allows a prolonged retrospective diagnosis of myocardial infarction. Further, while the amount of LD-2 in the blood is usually higher than the amount of LD-1, patients with acute myocardial infarction have more LD-1 than LD-2. This "flipped ratio" usually returns to
15 normal in 7 to 10 days. An elevated level of LD-1 with a flipped ratio has a sensitivity and specificity of approximately 75% to 90% for detection of acute myocardial infarction.

Elevated LDH levels have also been used as a prognostic indicator for cancers such as small cell lung carcinoma. Specifically, elevated levels of LDH indicate a poor prognosis for such diseases (Kawahara, et al., (1997) *Jpn J Clin Oncol.* 1997 Jun;27(3):158-
20 65).

LDH expression in cells has also been shown to be induced by interleukin-1 alpha, a major cytokine associated with, e.g., inflammation (Nehar et al. (1998) *Biol Reprod* Dec;59(6):1425-32).

Islet beta-cells express low levels of lactate dehydrogenase and have high glycerol
25 phosphate dehydrogenase activity. The effects on glucose metabolism and insulin secretion of acute overexpression of the skeletal muscle isoform of lactate dehydrogenase (LDH)-A in these cells have been studied by Ainscow EK et al. (*Diabetes* 2000 Jul;49(7):1149). The results of these studies have shown that overexpression of LDH activity interferes with normal glucose metabolism and insulin secretion in islet beta cells, and it may therefore be
30 directly responsible for insulin secretory defects in some forms of type 2 diabetes. These results also reinforce the view that glucose-derived pyruvate metabolism in the mitochondria is critical for glucose-stimulated insulin secretion in beta cells. Other data show that an overexpression of lactate dehydrogenase A attenuates glucose-induced insulin secretion in stable MIN-6 beta-cell lines, which normally express low levels of L-lactate

dehydrogenase (Zhao C, Rutter GA FEBS Lett. 1998 Jul 3;430(3):213-6). Low LDH activity thus appears to be important in beta-cell glucose sensing.

Analysis of the LDH isoenzyme pattern in CSF fluid has also been shown to be helpful in the evaluation of CNS involvement in patients with hematologic malignancies (Lossos IS, et al.

5 Cancer. 2000 Apr 1;88(7):1599-604).

It is believed that the protein of SEQ ID NO:255 is a lactate dehydrogenase protein, most likely of the LDH-A or M subtype. The activity of the present protein can be assessed using any standard method for detecting lactate dehydrogenase enzyme activity, including those involving the UV detection of pyruvate, a product of LDH-catalyzed enzymatic reactions.

10 In one embodiment, the polypeptides and polynucleotides of the invention are used to detect testis and liver tissue, as well as cells derived from these tissues. For example, nucleic acids and proteins of the invention can be labeled isotopically or chemically, using methods known to those skilled in the art, and used as probes in northern blots, far-western blots and *in situ* hybridization experiments. An ability to detect specific cell types is useful, e.g. for the determination of the
15 history of tumor cells, as well as for the identification of cells and tissues for histological studies.

In another embodiment, the present protein can be used in any of a variety of clinical assays involving LDH enzymes. For example, the protein can be used as a coupling enzyme to determine the enzymatic activity of various amino-transferases, such as alanine aminotransferase (ALT), as detected by UV spectrometry of the produced pyruvic acid. Such assays have significant clinical
20 utility, as amino-transferases are enzymes which show high activity in liver, heart, kidney, etc. and show remarkable increases in serum in association with various diseases. The protein of the invention can also be used as a coupling enzyme to help determine the level of substrates such as urea, as the enzyme promotes the conversion of such substances into pyruvic acid which can be detected by UV spectrometry.

25 In another embodiment, the present protein can be used to identify ingredients for cosmetic formulations. Specifically, enhancers of lactate dehydrogenase can be included in cosmetic compositions to stimulate keratinocyte proliferation and collagen synthesis in cutaneous tissues. The inhibitors can be combined with other active ingredients such as pyruvic acid, acetic acid, acetoacetic acid, beta-hydroxybutyric acid, Krebs cycle pathway metabolites, aliphatic saturated or
30 unsaturated fatty acids containing from 8 to 26 carbon atoms, omega-hydroxy acids containing from 22 to 34 carbon atoms, glutamic acid, glutamine, valine, alanine, leucine, and mixtures thereof (see, e.g., US Patent 5,853,742, the disclosure of which is hereby incorporated by reference in its entirety).

In another embodiment, the present invention provides methods for treating or preventing
35 cancer, e.g., by inhibiting lactate dehydrogenase activity in cells, preferably specifically the cancer cells, of a patient. The expression or activity of lactate dehydrogenase can be inhibited using any of a large number of agents, including, but not limited to, antibodies, antisense molecules, ribozymes,

and heterologous molecules that inhibit the expression or activity of the lactate dehydrogenase in the cancer cells of the patient. In one embodiment, lactate dehydrogenase that has been obtained from a primate, or anti-lactate dehydrogenase antibodies obtained from a mammal as a result of the parenteral administration of primate lactate dehydrogenase to said mammal, is parenterally administered to human cancer patients. Antibodies derived from the protein of the invention or part thereof can also be used to inhibit cancer cell development as described in US Patent No. 4,620,972.

Analysis of the LDH isoenzyme pattern in CSF fluid has been shown to be helpful in the evaluation of CNS involvement in patients with hematologic malignancies (Lossos IS, et al. Cancer. 2000 Apr 1;88(7):1599-604). Thus, in another embodiment, the protein of SEQ ID NO:255 can be used to develop assays to monitor the LDH isoenzyme activity in CSF fluid, thereby improving the sensitivity of CSF cytology. This assay may be derived, e.g., from the methods described by Short S. et al. (J Biol Chem. 2000 Apr 28;275(17):12963-9).

In another embodiment, the protein of SEQ ID NO:255 is used to detect and/or treat insulin secretory defects in some forms of type 2 diabetes. For example, various evidence indicates that LDH overexpression may be involved in certain types of diabetes. Therefore, the detection of an elevated level of LDH in a patient, e.g. in pancreatic islet cells of a patient, can be used as an indication that the patient has diabetes, or is at risk of developing diabetes. Similarly, methods of inhibiting the expression or activity of LDH in those cells, e.g. using antibodies, antisense sequences, or heterologous compounds that inhibit the expression or activity of LDH, can be used to treat or prevent diabetes.

In another embodiment, the protein of the invention can be used to eliminate endogenous pyruvic acid in cells in vitro or in vivo.

In another embodiment, the expression of the present protein is used as a marker for interleukin 1, e.g. IL-1 alpha, activity in cells or in a patient. Specifically, as it has been shown that LDH expression is induced by IL-1 alpha, then the expression, or elevated expression, of the present protein can be used as a marker for the action of IL-1 on the cell. As IL-1 has been implicated in a number of physiological processes, including inflammation and more specifically in deleterious processes such as arthritis and autoimmune disorders, the present protein can serve as a marker for the presence of such disorders, or for a predisposition for the disorders.

In another embodiment, the present protein is used to detect heart disease and other diseases in patients. For example, levels of LDH are known to rise following myocardial infarction and other heart ailments. Accordingly, the detection of an elevated level of the protein of the invention, alone or in view of the levels of other proteins such as other LDH isozymes, can be used as an indicator of a heart attack or other diseases, including leukemia. The levels of LDH can be assessed in any tissue or biological sample, including, but not limited to, serum, and can be detecting using any standard method, including, but not limited to, immunoassays and assays for LDH enzyme activity.

In another embodiment, the present protein is used to determine a prognosis for any of a number of diseases, including cancers such as small cell lung carcinoma. For example, the level of the present protein is detected in the serum of a patient suffering from cancer, wherein the detection of a decreased level of expression or activity of the protein indicates a worse prognosis for the patient compared to the prognosis in a patient with a normal level of the protein activity or expression.

Proteins of SEQ ID NOs:243, 253 (internal designation numbers 105-016-1-0-D3-CS and 105-095-2-0-G11-CS)

The 331-amino-acid- long protein of SEQ ID NO:243, encoded by the cDNA of SEQ ID NO:2, is found in prostate and in fetal brain and is homologous to a secreted human protein (Genseq accession number Y59685). In addition, this protein is highly homologous to the putative glycerophosphodiester phosphodiesterase (GP-PDE) MIR16 (Membrane Interacting protein of RGS16) protein (SPTREMBLNEW SPTREMBL SWISSPROT accession number AAF65234) encoded by the cDNA of GENPEPT GENPEPTNEW accession number AF212862; in fact, the protein of the invention is a likely variant of the MIR16 protein. Furthermore, a BLAST search with the amino acid sequence of SEQ ID NO:243 indicates that the protein of the invention is homologous to GP-PDEs of *E.coli* (SWISSPROT accession numbers P09394 and P10908) and *Haemophilus influenzae* (SWISSPROT accession number Q06282). The protein of SEQ ID NO:243 displays 2 candidate membrane-spanning segments, from amino acids 7 to 27 and 258 to 278, and a putative signal peptide from amino acids 19 to 24. Finally, the protein of the invention has two putative *N*-glycosylation sites: asparagine residues at positions 168 and 198 (Zheng *et al.*, Proc. Natl. Acad. Sci. 97 :3999-4004 (2000)).

The cDNA of SEQ ID NO:2 differs from the cDNA of GENPEPT GENPEPTNEW accession number AF212862 by its extended 5' and 3' termini, and from the cDNA of SEQ ID NO:12 by polymorphisms and alternate splicings.

The MIR16 (Membrane Interacting protein of RGS16) protein, which is homologous to the protein of the invention, was identified in a yeast two-hybrid screen of a pituitary cell cDNA library using the RGS16 (Regulator of G protein Signaling) protein as bait (Zheng *et al.*, Proc. Natl. Acad. Sci. 97:3999-4004 (1999)). and Sasaki, J. Bacteriol. 175:4569-4571 (1993); Zheng *et al.*, *ibid.*). Remarkably, the GP-PDE from *Haemophilus influenzae* (also called protein D) which is 67% identical to the periplasmic GP-PDE of *E.coli*, presents affinity for human immunoglobulin D (Janson *et al.*, Infect. Immun. 62:4848-854 (1994)).

From sequence alignments, it can be seen that the N-terminal region of MIR16 (amino acids 70-150), immediately after the putative signal peptide, is highly conserved (40-61% similarity), suggesting that it may contain residues critical for catalytic activity, i.e., the catalytic site. GP-PDEs hydrolyze deacetylated phospholipid GPs, such as glycerophosphocholine (GPC)

and glycerophosphoethanolamine, to sn-glycerol-3-phosphate (G3P) and the corresponding alcohols (Zheng *et al.*, *ibid.*). The putative enzymatic activity of MIR16 and its interaction with RGS16 suggest that it may play important roles in lipid metabolism and in G protein signaling. As shown in northern blot experiments, the MIR16 mRNA is highly transcribed in heart, liver, kidney, testis and brain. The observed expression of MIR16 in the brain is consistent with the above-described expression of the protein of the invention in the fetal brain.

It is believed that the proteins of SEQ ID NOs:243 and 253 or part thereof are members of the glycerophosphodiester phosphodiesterase protein family, interact with the RGS16 protein and, as such, play important roles in both lipid metabolism and in G protein signaling. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:243 from positions 7 to 27, 19 to 24 and 258 to 278. Other preferred polypeptides of the invention are fragments of SEQ ID NO:243 or 253 having any of the biological activities described herein. Additional preferred polypeptides are those that comprise asparagine residues at positions 168 and/or 198.

The invention first relates to methods and compositions using cDNAs of SEQ ID NO:2 or 12 or part thereof, and proteins of the invention SEQ ID NO:243 or 253 or part thereof to identify specific cell types, preferably from prostate or fetal brain. For example, nucleic acids and proteins of the invention are labeled isotopically or chemically following methods known to those skilled in the art, and further used as probes in northern blots, far-western blots and *in situ* hybridization detection experiments. An ability to detect specific cell types is useful, e.g. for the determination of the history of tumor cells, as well as for the identification of cells and tissues for histological studies.

Any of a number of *in vitro* assays can be used to detect SEQ ID NO:243 or 253 protein activity, for example for *in vitro* screening of modulators of protein activity. Preferably cDNA encoding the protein of the invention is cloned in a prokaryotic expression vector, according to methods known to those skilled in the art. Briefly, the GP-PDE activity of the recombinant protein is analyzed by a coupled spectrophotometric assay as described by Larson and collaborators and adapted by Cameron and collaborators (Larson *et al.*, *J. Biol. Chem.* 258 :5426-5432 (1983); Cameron *et al.*, *Infect. Immun.* 66 :5763-5770 (1998)). Such enzymatic activity may be measured *in vitro* in the presence of modulating drugs.

Another embodiment of the present invention relates to methods of using the protein of the invention or part thereof to purify or specifically bind to human immunoglobulin D. Several immunoglobulin (Ig) binding bacterial cell wall proteins have been isolated and/or cloned during the last two decades. The best characterized of these are protein A of *Staphylococcus aureus* (which binds to human IgG subclasses 1, 2 and 4, IgG of several mammals species, and in some instances human Ig of classes A, M, E), and protein G of group G beta-hemolytic streptococci (which binds to all human IgG subclasses and which also displays a wider binding spectrum for

animal IgG than protein A). IgD binds to neither protein A nor protein G. Consequently, it is of great interest to identify new proteins capable of binding IgD, thereby allowing its separation and purification. In addition, IgD binding proteins can also be used in immunoprecipitation procedures with IgD, as are routinely performed with proteins A and G in the case of IgG. The binding and
5 purification of IgD using the protein of the invention can be accomplished in any of a number of ways, for example by generating a fusion protein or polypeptide in which the protein of the invention or part thereof, is combined with another protein by the use of a recombinant DNA molecule. The resulting fusion product including the protein of the invention or part thereof is then covalently, or by any other means, bound to a protein, carbohydrate or matrix (such as gold,
10 “Sephadex” particles, polymeric surfaces). Such a complex is very useful for IgDs immobilization and consecutive immunoprecipitations in batch. Similar assays for binding of protein D (GP-PDE) of *Haemophilus influenzae* and IgD are described in the US Patent No. 6,025,484.

Another embodiment of the invention relates to compositions and methods using the protein of the invention, or part thereof, as GP-PDE enzymes to hydrolyze deacylated phospholipids (GPs),
15 such as glycerophosphocholine (GPC) and glycerophosphoethanolamine, to sn-glycerol-3-phosphate (G3P) and the corresponding alcohols. First, this enzymatic activity, which belongs to the class of specific phospholipase D, makes the protein of the invention very useful to study biological membranes and their phospholipidic components. Moreover, as glycerophospholipids are major components of the lipidic bilayer, elimination of their hydrophilic moiety using the GP-
20 PDE activity of the protein of the invention would likely modify the structure and consequently the permeability of eukaryotic cell membranes. Such modifications could improve the transfection efficiency of eukaryotic cells, in vitro or in vivo. Typically, in such embodiments the purified protein of SEQ ID NOs:243 or 253 is administrated to cells; purified proteins of the invention can be obtained in any of a number ways, for example by inserting the cDNA encoding the proteins into
25 a prokaryotic expression vector using any technique known to those skilled in the art. The recombinant protein produced and purified in the prokaryotic system is then added to an *in vitro* culture of eukaryote cells before or during transfection. The recombinant protein of the invention can also be used to increase the efficiency of cell transfection *in vivo*, most notably in the case of gene therapy. For example, tumoral masses are very often resistant to transfection, and the protein
30 of the invention would likely provide an effective way to facilitate the introduction of cytotoxic genes (such as pro-apoptotic genes) or antitumoral drugs in solid tumors.

Still another embodiment of the protein of the invention relates to methods and compositions to diagnose, treat, and prevent disorders associated with excess glutamate signaling in the brain. As described above, the MIR16 protein interacts physically with the RGS16 protein
35 (Regulator of G protein Signaling 16). Receptors of many hormones use heterotrimeric G proteins for signal transduction after ligand binding (for a review, see Neer, Cell 80 :249-257 (1995)). Among these receptors are metabotropic glutamate receptors (mGluRs). These receptors, which are

expressed in the brain, like the protein of the invention, are a novel family of cloned G-protein-coupled receptors (Schoepp and Conn, Trends Pharmacol. Sci. 14:13-20 (1993)). Endogenous glutamate, by activating the mGluR1 receptor (and also NMDA and AMPA receptors), may contribute to the brain damage occurring acutely after epilepsy, cerebral ischemia or traumatic brain injury. It may also contribute to chronic neurodegeneration in such disorders as amyotrophic lateral sclerosis and Huntington's chorea (Meldrum, J. Nutr. 130(4S Suppl):1007S-1015S (2000)).

The invention thus relates to methods and compositions using cDNAs of SEQ ID NO:2 or 12 or part thereof, and proteins of SEQ ID NO:243 or 253 or part thereof, to diagnose, treat, or prevent disorders associated with excess glutamate signaling in the brain. Specifically, the level of activity or expression of the proteins can be correlated with the level of glutamate signaling, or with the glutamate-signaling associated brain damage involved in epilepsy, cerebral ischemia, traumatic brain damage, ALS, or Huntington's chorea, or with any other G-protein associated physiological process or disease or condition. For situations where the level of the expression or activity of the protein is positively correlated with such signaling or with the presence of a disease or condition, the signaling, disease or condition can be detected using any of a number of tools for detecting protein expression or activity, including northern blots, far-western blots and *in situ* hybridization experiments, where an elevated level of the protein, protein activity, or nucleic acid of the invention indicates the presence of the disease, condition, or signaling process. Further, such diseases or conditions can be treated or prevented, or such signaling pathways can be inhibited, using compounds that inhibit the expression or activity of the protein, such as antibodies, antisense molecules, ribozymes, dominant negative forms of the protein, or any heterologous molecule that inhibits protein activity or expression. Alternatively, where the expression or activity of the protein of the invention is negatively associated with the signaling pathway, disease or condition, a detection of a decreased level of expression or activity of the protein can be used to indicate the presence of the disease, condition, or pathway. Further, in such cases, the disease or condition can be treated or prevented, or the pathway be inhibited, using any compound that increases the activity or level of the protein, such as nucleic acids encoding the protein, the protein itself, or heterologous compounds that cause an increase in the level of protein expression or activity.

Protein of SEQ ID NO:386 (internal designation 105-037-4-O-H12-CS)

The protein of SEQ ID NO:386, encoded by the cDNA of SEQ ID NO:145, is strongly expressed in the fetal brain and uterus. The 207-amino-acid-long protein of SEQ ID NO:386 displays pfam SPRY domains from positions 85 to 205.

SPRY domains have been found in a number of proteins involved in multiple cellular and developmental processes. For example, the Midline-1/FXY family of proteins has been shown to associate with microtubules, and has been implicated in human diseases, such as Opitz Syndrome, a congenital disorder characterized by multiple developmental abnormalities (see, e.g., Cainarca, et

al., (1999) Hum Mol Genet 8(8):1387-96). In addition, the cytoplasmic Marenostirin/Pyrin protein has been demonstrated to be the cause of Familial Mediterranean fever, an autosomal recessive disorder characterized by fever and serositis (Nat Genet 1997 Sep;17(1):25-31). Other SPRY proteins include SplA, a serine protease from *Staphylococcus aureus*, and butyrophilin, a major milk protein. Another family of proteins known to contain the SPRY domain are the Ryanodine receptors (RyRs).

Ryanodine receptors play an important role in Ca^{2+} signaling in muscle and non muscle cells by releasing Ca^{2+} from intracellular stores. For example, these receptors are centrally important in excitation-contraction (e-c) coupling, which occurs at specialized regions where the sarcoplasmic reticulum (SR), containing the ryanodin receptors, and the plasma membrane/transverse-tubule system form junctions. RyRs are also thought to play some role in maintaining the structural integrity of the SR-T-tubule junctions. RyR is apparently unable to carry out the requisite functions associated with e-c coupling by itself, however, because it forms interactions with other macromolecules at the triad junction. For example, two small proteins, calmodulin and FKBP12, are believed to modulate RyR at the triad junction.

It is believed that mammalian tissues express three different RyR isoforms, comprising four 560-kDa (RyR polypeptide) and four 12-kDa (FK506 binding protein) subunits. It is believed that these large protein complexes conduct monovalent and divalent cations and are capable of multiple interactions with other molecules. The subunits of the protein complexes include small diffusible endogenous effector molecules including Ca^{2+} , Mg^{2+} , adenine nucleotides, sufhdryl modifying reagents (glutathione, NO, and NO adducts) and lipid intermediates, and proteins such as protein kinases and phosphatases, calmodulin, immunophilins (FK506 binding proteins), and in skeletal muscle the dihydropyridine receptor. The RyR from skeletal muscle is the major calcium release channel for that tissue, and the most intensively studied of the three genetic isoforms detected thus far in mammalian species. The other two RyR isoforms are often referred to as the 'heart' and 'brain' forms, but the actual cell and tissue distribution of the isoforms is complex.

Because of their multiple ligand interactions, ryanodin receptors constitute an important, potentially rich pharmacological target for controlling cellular functions. Ca^{2+} release channel activity is modulated by many endogenous effectors, including Ca^{2+} , ATP, Mg^{2+} , and calmodulin. In addition, many exogenous effectors, including caffeine, local anesthetics, and polyamines, also modify channel activity. For example, tetracaine, procaine, benzocaine, and lidocaine inhibit Ca^{2+} release from the SR. They appear to interact with a specific site(s) located on the RYR, affecting both ryanodin-binding and single channel activities (Shoshan-Barmatz et al. 1993; J. Membr. Biol.; 133; 171-181).

The importance of intracellular calcium as a second messenger in cellular signal transduction processes is well established. Alterations in intracellular Ca^{2+} homeostasis have profound effects on many cell functions, including secretion, contraction-relaxation, motility,

metabolism, protein synthesis, modification and folding, gene expression, cell-cycle progression and apoptosis. A major source of cytoplasmic calcium is from intracellular storehouses located in the endoplasmic reticulum, or in muscle, within the sarcoplasmic reticulum (SR).

Given that cellular Ca^{2+} handling is an important factor in the control of neuronal metabolism and electrical activity, abnormalities of intracellular Ca^{2+} channels might be expected to contribute to some forms of epilepsy or to anoxic brain damage following an episode of cerebral ischemia. Cell loss is said to be a characteristic feature of degenerative brain disorders, including Alzheimer's disease. It is well established that neuronal cell death may be secondary to an abnormal elevation of cytoplasmic Ca^{2+} , particularly that associated with activation of excitatory glutamate receptors (e.g., in epilepsy). This strongly suggests that the release of stored Ca^{2+} contributes to nerve cell damage and cell death in various circumstances.

It is believed that the protein of SEQ ID NO:386 is functionally related to other SPRY-containing proteins, such as the ryanodine receptors, Marenostin/Pyrin, SplA, Midline-1/FXY, and butyrophilin. Accordingly, it is thus believed that the present protein is associated with the release of Ca^{2+} from intracellular Ca^{2+} -storing organelles, like the endoplasmic reticulum and, in muscle, the sarcoplasmic reticulum (SR), as well as being involved in microtubule binding. Preferred polypeptides of the invention are any fragments of SEQ ID NO:386 having any of the biological activities described herein.

In one embodiment, the present protein and nucleic acids can be used to specifically detect cells of the fetal brain and uterus, as the protein is overexpressed in these tissues. For example, the protein of the invention or part thereof may be used to synthesize specific antibodies using any technique known to those skilled in the art. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, such as in forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, etc., or to differentiate different tissue types in a tissue cross-section using immunochemistry. The protein can also be used to specifically label microtubules in cells.

In another embodiment, the protein of the invention or part thereof may be used in regulating intracellular Ca^{2+} levels. As alterations in intracellular Ca^{2+} homeostasis have profound effects on many cell functions, including secretion, contraction-relaxation, motility, metabolism, protein synthesis, modification and folding, gene expression, cell-cycle progression and apoptosis, the ability to modulate intracellular Ca^{2+} levels provides a tool to alter any of these cellular functions, in vitro or in vivo. Such an ability has wide utility for a large number of applications, for example to manipulate the behavior (e.g. growth rate, secretion, survival, etc.) of cells grown in vitro, as well as to treat, prevent, or diagnose any of a number of diseases associated with altered Ca^{2+} signaling in vivo. The activity or expression of the protein of the invention can be modulated in any of a large number of ways, for example by administering to cells or to a patient the protein itself, a polynucleotide encoding the protein, antibodies, antisense sequences, dominant negative

forms of the protein, compounds that alter the expression or activity of the protein, etc. The effect of any such agent on calcium flux in cells can be detected using standard methods, including by studying the permeation of Ca^{2+} release through endoplasmic reticulum (ER) and sarcoplasmic reticulum (SR) channels using tracers, light scattering and fluorescence quenching, and channel
5 reconstitution in planar bilayer. In addition, targeted recombinant photoproteins can provide direct measurements of organellar Ca^{2+} (Montero et al.; 1995; EMBO J.; 14, 5467-5475).

The invention further relates to methods and compositions using the protein of the invention or part thereof to diagnose, prevent and/or treat several disorders in which the activity or recognition of ryanodin receptors, is impaired or excessive. These disorders include, but are not
10 limited to, neurodegenerative diseases, cardiovascular disorders, severe myasthenia, malignant hyperthermia, epilepsy, and central core disease. For example, in patients with severe myasthenia, the level of anti-RyR antibodies has been directly related to the severity of the disease (Skeie et al., 1996: Eur. J. Neurol. 3; 136-140). There is also some evidence to suggest that RyR abnormalities are a primary cause of many types of cardiac disease. In addition, the protein of the invention can
15 be used to diagnose other diseases associated with SPRY-protein dysfunction, such as Familial Mediterranean fever and Opitz syndrome. Finally, as SPRY containing proteins have been implicated in embryonic development (e.g. the Midline1 protein), the protein and nucleic acids of the invention can be used to detect developmental disorders, as the detection of a mutation in the gene encoding SEQ ID NO:386, or a detection of abnormal gene expression in a fetus, can be used
20 to indicate the presence of a developmental abnormality. For example, as the protein of SEQ ID NO:386 is strongly expressed in the fetal brain, it is likely that the protein plays a role in the normal development of the brain in utero.

The present invention also relates to diagnostic assays for detecting altered levels of the protein of SEQ ID NO:386 in various tissues, as over-expression of the protein compared to normal
25 control tissue samples can indicate the presence of certain disease conditions such as neurodegenerative disorders, cardiovascular disorders, severe myasthenia, malignant hyperthermia, epilepsy, and central core disease. Assays used to detect levels of the polypeptide of the present invention in a sample derived from a host are well-known to those of skill in the art and include radioimmunoassays competitive-binding assays, Western Blot analysis and ELISA assays.

30 Proteins SEQ ID NOs:283 and 286 (internal designations 174-38-1-0B6-CS_LA and 174-41-1-0-A6-CS LA)

The protein of SEQ ID NO:283, encoded by the cDNA of SEQ ID NO:42, is overexpressed in salivary glands and to a lesser extent in bone marrow, and shows homology over the C-terminal length to the immunoglobulin (Ig) protein superfamily, which is conserved among eukaryotes
35 (including rabbit, rodents and human). In particular, the 468-amino-acid-long protein of the invention, which is similar in size to the constant chain of Ig related proteins, displays two pfam

conserved immunoglobulin domains, from position 205 to 285 and from position 318 to 384, which are known to be involved in the basic structure of the light and heavy constant chains of immunoglobulins. It is known (Orr H.T., Nature 282:266-270(1979)) that the Ig constant chain domains and a single extracellular domain in each type of MHC chain are closely related, sharing
5 over one hundred amino-acids of homology. All members of the Ig related superfamily, including the MHC class I alpha chain and beta-2-microglobulin, as well as the MHC class II alpha and beta chains, display the prosite conserved characteristic pattern around the C-terminal cysteine ([FY]-x-C-x-[VA]-x-H). This cysteine is involved in the disulfide bond between the light and heavy chains, and is also found in the protein of the invention (position 380 to 386). The protein of the invention
10 also exhibits an motif Ig and Major Histocompatibility Complex protein signature from positions 319 to 336. In addition, the protein of the invention displays homology with tapasin (GeneBank No. AF009510), a chaperone-like protein closely associated with TAP-binding proteins, which is well conserved among eukaryotes (chicken, rodents and human). Tapasin has been shown to increase the efficiency of antigen processing and presentation by mediating the association of MHC
15 complex proteins with TAP proteins to the endoplasmic reticulum and to the cell surface during immune response (for review see Abele, R. and Tampé, R., Bioch. et Biophysica Acta, 1999). In addition, the protein of the invention displays two transmembrane domains from positions 199 to 219 and from positions 406 to 426, a hydrophobic profile similar in amino acid position to the hydrophobic stretch of amino acids of human and mouse tapasin (Suling L., J. Biol. Chem.,
20 274:8649-8654, 1999), and a secreted signal peptide from position 9 to 23. Both signatures are largely present in Ig related proteins such as secreted antibodies or antigen presenting proteins. The invention also encompasses a variant (SEQ ID NO:286) of SEQ ID NO:283, encoded by the cDNA of SEQ ID NO:45. The protein of SEQ ID No:286 is a 442-amino-acid-long protein with a C-terminal shorter end of 26 amino-acids compared to the protein of SEQ ID NO:283. The variant of
25 SEQ ID NO:286, which results from a frameshift (position 1445 in SEQ ID NO:45) in the coding sequence that leads to a stop codon in the corresponding protein, displays characteristics identical to those described above in terms of motifs, Ig signatures, function, and potential uses.

The immunoglobulin (Ig) gene superfamily comprises a large number of cell surface glycoproteins that share sequence homology with the V and C domains of antibody heavy and light
30 chains. These molecules function as receptors for antigens, immunoglobulins and cytokines as well as adhesion molecules, and play important roles in regulating the complex cell interactions that occur within the immune system (A. F. Williams et al., Annu. Rev. Immuno. 6:381-405, 1988, T. Hunkapiller et al., Adv. Immunol. 44:1-63, 1989; for a short review see also Prosite entry PS00290)

The introduction of an antigen into a host initiates a series of events culminating in an
35 immune response. In addition, self-antigens can result in immunological tolerance or activation of an immune response against self-antigens. A major portion of the immune response is regulated by presentation of antigen by major histocompatibility complex molecules. MHC molecules bind to

peptide fragments derived from antigens to form complexes that are recognized by T cell receptors on the surface of T cells, giving rise to the phenomenon of MHC-restricted T cell recognition. The ability of a host to react to a given antigen (responsiveness) is influenced by the spectrum of MHC molecules expressed by the host. Responsiveness correlates with the ability of specific peptide
5 fragments to bind to particular MHC molecules.

There are two types of MHC molecules, class I and class II, each of which comprise two chains. In class I [2], the alpha chain is composed of three extracellular domains, a transmembrane region, and a cytoplasmic tail. The beta chain (beta-2-microglobulin) is composed of a single extracellular domain. In class II [3], both the alpha and the beta chains are composed of two
10 extracellular domains, a transmembrane region and a cytoplasmic tail. MHC class I molecules are expressed on the surface of all cells, and MHC class II molecules are expressed on the surface of antigen presenting cells. MHC class II molecules bind to peptides derived from proteins made outside of an antigen presenting cell. In contrast, MHC class I molecules bind to peptides derived from proteins made inside a cell. In order to present peptide in the context of a class II molecule, an
15 antigen presenting cell phagocytoses an antigen into an intracellular vesicle, in which the antigen is cleaved, bound to an MHC class II molecule, and then returned to the surface of the antigen presenting cell.

Major histocompatibility complex (MHC) class I molecules present antigenic peptides to CD8 T cells (Townsend, A. et al., Nature:340,443-448)). The peptides are generated in the cytosol
20 and then translocated across the membrane of the endoplasmic reticulum by the transporter associated with antigen processing (TAP). TAP is a trimeric complex consisting of TAP1, TAP2, and tapasin (TAP-A). TAP1 and TAP2 are required for the peptide transport. Tapasin mediates the interaction of MHC class I HC-beta-2 microglobulin with TAP, and this interaction is essential for peptide loading onto MHC class I HC-beta-2-microglobulin (Suling et al., J. Biol. Chem.,
25 274:8649-8654). T cell receptors (TCRs) are the second antigen recognition molecules, and recognize antigens that are bound by MHC molecules. Recognition of MHC complexed with peptide (MHC-peptide complex) by TCR can effect the activity of the T cell bearing the TCR. Thus, MHC-peptide complexes are important in the regulation of T cell activity and, thus, in regulating an immune response.

30 Human cytomegalovirus (HCMV) is a betaherpesvirus which causes clinically serious disease in immunocompromised and immunosuppressed adults, as well as in some infants infected in utero or perinatally (Alford, C. A., and W. J. Britt. 1990. Cytomegalovirus, p. 1981-2010. In D. M. Knipe and B. N. Fields (ed.), Virology, 2nd ed. Raven press, New York). In human cytomegalovirus (HCMV)-infected cells, expression of the cellular major histocompatibility
35 complex (MHC) class I heavy chains is down-regulated, where down-regulation is defined as reduction in either synthesis, stability or surface expression of MHC class I heavy chains. A similar phenomenon has been reported for some other DNA viruses, including adenovirus, murine

cytomegalovirus, and herpes simplex virus (Anderson, M., et al., Cell 43:215-222, 1985; Burgert and Kvist, Cell 41:987-997, 1985; Heise T. M., et al., J. Exp. Med. 187:1037-1046, 1998). In the adenovirus and herpes simplex virus systems, the product of a viral gene which is dispensable for replication in vitro is sufficient to cause down-regulation of MHC class I heavy chains (Anderson, M., et al., 1985, supra). The gene(s) involved in class I heavy chain down-regulation by murine cytomegalovirus have not yet been identified.

It is believed that the proteins of SEQ ID NOs:283 and 286 are members of the immunoglobulin superfamily and, as such, play a role in the immune response, cellular proteolysis, cell proliferation and differentiation, pathogen recognition, apoptosis, and other processes associated with the Ig superfamily. In addition, the proteins of the invention are thought to be tightly linked to the antigen processing and presentation system in the context of peptide assembly and translocation of foreign peptides across endoplasmic reticulum and cell surface membranes as new chaperonin-like proteins associated with MHC I and TAP proteins. The weak homology (30%) with the TAP protein family is thought to indicate the specificity of the interactions of the proteins of the invention with MHC proteins and/or TAP-related proteins, as described by Suling et al., supra.

Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:283 from position 9 to 23, 199 to 219, 205 to 285, 318 to 384, 319 to 336, 380 to 386 and from 406 to 426. Other preferred polypeptides of the invention are fragments of SEQ ID NO:283 having any of the biological activities described herein.

In one embodiment, the invention relates to methods and compositions for using the protein of the invention or part thereof as a marker protein to selectively identify tissues, such as salivary glands and bone marrow tissues, which strongly express the protein of the invention. For example, the protein of the invention or part thereof may be used to synthesize specific antibodies using any techniques known to those skilled in the art including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry.

In another embodiment, the invention relates to methods for using the protein of the invention to visualize proteins and peptides involved in antigen recognition system within cells by virtue of their physical interaction with the proteins of the invention. For example, the protein may be used to detect the presence and/or the localization of MHC peptides and TAP-like proteins in a cell. The protein of the invention, and hence any interacting proteins, can be labeled using any of a number of methods, including by binding with specific antibodies or by creating a fusion protein comprising the protein of the invention as well as a readily detectable moiety, such as an epitope tag, biotin, or green fluorescent protein.

In another embodiment, polynucleotide or polypeptide sequences of the invention or part thereof may be used for the diagnosis of a disorder associated with a loss of regulation of the expression of the protein of the invention, preferably, but not limited to, deficiencies of the MHC protein system. Examples of such disorders include, but are not limited to, acquired

5 immunodeficiency syndrome (AIDS), X-linked agammaglobinemia of Bruton, common variable immunodeficiency (CVI), DiGeorge's syndrome (thymic hypoplasia), thymic dysplasia, isolated IgA deficiency, severe combined immunodeficiency disease (SCID), immunodeficiency with thrombocytopenia and eczema (Wiskott-Aldrich syndrome), Chediak-Higashi syndrome, chronic granulomatous diseases, hereditary angioneurotic edema, immunodeficiency associated with

10 Cushing's disease, Addison's disease, adult respiratory distress syndrome, allergies, ankylosing spondylitis, amyloidosis, anemia, asthma, atherosclerosis, autoimmune hemolytic anemia, autoimmune thyroiditis, bronchitis, cholecystitis, contact dermatitis, Crohn's disease, atopic dermatitis, dermatomyositis, diabetes mellitus, emphysema, episodic lymphopenia with lymphocytotoxins, erythroblastosis fetalis, erythema nodosum, atrophic gastritis,

15 glomerulonephritis, Goodpasture's syndrome, gout, Graves' disease, Hashimoto's thyroiditis, hypereosinophilia, irritable bowel syndrome, multiple sclerosis, myasthenia gravis, myocardial or pericardial inflammation, osteoarthritis, osteoporosis, pancreatitis, polymyositis, psoriasis, Reiter's syndrome, rheumatoid arthritis, scleroderma, Sjogren's syndrome, systemic anaphylaxis, systemic lupus erythematosus, systemic sclerosis, thrombocytopenic purpura, ulcerative colitis, uveitis,

20 Werner syndrome, complications of cancer, hemodialysis, and extracorporeal circulation, leukemias such as multiple myeloma, and lymphomas such as Hodgkin's disease; a cell proliferative disorder such as arteriosclerosis, atherosclerosis, bursitis, cirrhosis, hepatitis, mixed connective tissue disease (MCTD), myelofibrosis, paroxysmal nocturnal hemoglobinuria, polycythemia vera, psoriasis, primary thrombocythemia, and cancers including adenocarcinoma, leukemia, lymphoma,

25 melanoma, myeloma, sarcoma, teratocarcinoma, and, in particular, cancers of the adrenal gland, bladder, bone, bone marrow, brain, breast, cervix, gall bladder, ganglia, gastrointestinal tract, heart, kidney, liver, lung, muscle, ovary, pancreas, parathyroid, penis, prostate, salivary glands, skin, spleen, testis, thymus, thyroid, and uterus; and an infection, such as infections by viral agents classified as adenovirus, arenavirus, bunyavirus, calicivirus, coronavirus, filovirus, hepadnavirus,

30 herpesvirus, flavivirus, orthomyxovirus, parvovirus, papovavirus, paramyxovirus, picornavirus, poxvirus, reovirus, retrovirus, rhabdovirus, and togavirus; infections by bacterial agents classified as pneumococcus, staphylococcus, streptococcus, bacillus, corynebacterium, clostridium, meningococcus, gonococcus, listeria, moraxella, kingella, haemophilus, legionella, bordetella, gram-negative enterobacterium including shigella, salmonella, and campylobacter, pseudomonas,

35 vibrio, brucella, francisella, yersinia, bartonella, norcardium, actinomyces, mycobacterium, spirochaetale, rickettsia, chlamydia, and mycoplasma; infections by fungal agents classified as aspergillus, blastomyces, dermatophytes, cryptococcus, coccidioides, malassezia, histoplasma, and

other fungal agents causing various mycoses; and infections by parasites classified as plasmodium or malaria-causing, parasitic entamoeba, leishmania, trypanosoma, toxoplasma, pneumocystis carinii, intestinal protozoa such as giardia, trichomonas, tissue nematodes such as trichinella, intestinal nematodes such as ascaris, lymphatic filarial nematodes, trematodes such as schistosoma, and cestodes such as tapeworm. To assess abnormal expression of the present protein associated with any of these disorders, the level of the present polynucleotides or polypeptides can be detected in a biological sample or cell using any standard method, including Southern or northern analysis, dot blots, other membrane-based technologies, PCR technologies, dipstick, pin, ELISA assays, and in microarrays. Any of these methods may be used for the diagnosis of disorders characterized by an alteration of expression of SEQ ID NO:283 or 286, such as the disorders mentioned above, or in assays to monitor patients being treated with SEQ ID NO:283 or 286 or agonists, antagonists, or inhibitors of SEQ ID NO:283 or 286. Antibodies useful for diagnostic purposes may be prepared, e.g., in the same manner as that described in U.S. Patent No. 6,135,941. Diagnostic assays for SEQ ID NO:283 or 286 include methods which utilize the antibody and a label to detect SEQ ID NO: 283 or 286 in human body fluids or in extracts of cells or tissues. The antibodies may be used with or without modification, and may be labeled by covalent or non-covalent attachment of a reporter molecule. A wide variety of reporter molecules, several of which are described above, are known in the art and may be used.

In another embodiment, the protein of SEQ ID NO:283 or 286 or a fragment or derivative thereof may be administered to a subject to diagnose, treat or prevent an immune disorder associated with decreased expression or activity of the protein of the invention. Such disorders can include, but are not limited to, acquired immunodeficiency syndrome (AIDS), X-linked agammaglobulinemia of Bruton, common variable immunodeficiency (CVI), DiGeorge's syndrome (thymic hypoplasia), thymic dysplasia, isolated IgA deficiency, severe combined immunodeficiency disease (SCID), immunodeficiency with thrombocytopenia and eczema (Wiskott-Aldrich syndrome), Chediak-Higashi syndrome, chronic granulomatous diseases, hereditary angioneurotic edema, immunodeficiency associated with Cushing's disease, Addison's disease, adult respiratory distress syndrome, allergies, ankylosing spondylitis, amyloidosis, anemia, asthma, atherosclerosis, autoimmune hemolytic anemia, autoimmune thyroiditis, bronchitis, cholecystitis, contact dermatitis, Crohn's disease, atopic dermatitis, dermatomyositis, diabetes mellitus, emphysema, episodic lymphopenia with lymphocytotoxins, erythroblastosis fetalis, erythema nodosum, atrophic gastritis, glomerulonephritis, Goodpasture's syndrome, gout, Graves' disease, Hashimoto's thyroiditis, hypereosinophilia, irritable bowel syndrome, multiple sclerosis, myasthenia gravis, myocardial or pericardial inflammation, osteoarthritis, osteoporosis, pancreatitis, polymyositis, psoriasis, Reiter's syndrome, rheumatoid arthritis, scleroderma, Sjogren's syndrome, systemic anaphylaxis, systemic lupus erythematosus, systemic sclerosis, thrombocytopenic purpura, ulcerative colitis, uveitis, Werner syndrome, complications of cancer, hemodialysis, and extracorporeal circulation, leukemias

such as multiple myeloma, and lymphomas such as Hodgkin's disease. In addition, such disorders associated with decreased protein expression or activity can be treated by administering to a patient polynucleotide sequences encoding the protein of the invention, e.g. inserted in an appropriate vector. In another example, a compound that increases either the activity of the protein of the invention or their expression can be administered to a patient to treat or prevent any of the diseases mentioned above.

In a further embodiment, an antagonist of the protein of the invention may be administered to a subject to treat or prevent an immune disorder associated with increased expression or activity of the protein of SEQ ID NO:283 or 286 including, but not limited to, auto-immune diseases or graft rejection. In one aspect, an antibody which specifically binds the protein of the invention may be used directly as an antagonist or indirectly as a targeting or delivery mechanism for bringing a pharmaceutical agent to cells or tissues which express the proteins of the invention, such as the salivary gland tissue or the bone marrow tissue. In addition, sense, antisense nucleotides, GSE, ribozymes, specific protein inhibitors such as antibodies or small compounds can be administered to inhibit the expression of the proteins of the invention.

In another embodiment, an antagonist of the protein of SEQ ID NO:283 may be administered to a subject to treat or prevent a cell proliferative disorder. Such disorders may include, but are not limited to, arteriosclerosis, atherosclerosis, bursitis, cirrhosis, hepatitis, mixed connective tissue disease (MCTD), myelofibrosis, paroxysmal nocturnal hemoglobinuria, polycythemia vera, psoriasis, primary thrombocythemia, and cancers including adenocarcinoma, leukemia, lymphoma, melanoma, myeloma, sarcoma, teratocarcinoma, and, in particular, cancers of the adrenal gland, bladder, bone, bone marrow, brain, breast, cervix, gall bladder, ganglia, gastrointestinal tract, heart, kidney, liver, lung, muscle, ovary, pancreas, parathyroid, penis, prostate, salivary glands, skin, spleen, testis, thymus, thyroid, and uterus. In one aspect, an antibody which specifically binds the protein of the invention may be used directly as an antagonist or indirectly as a targeting or delivery mechanism for bringing a pharmaceutical agent to cells or tissue which express the protein of the invention. In another example, sense, antisense nucleotides, GSE, or ribozymes designed from nucleotides of the invention can be administered to inhibit the expression of the protein of the invention.

30 Protein of SEQ ID NO: 411 (internal designation 181-10-1-0-C9-CS)

The protein of SEQ ID NO: 411 encoded by the cDNA of SEQ ID No: 170 is highly expressed in fetal liver. The protein of the invention is homologous to peripheral benzodiazepine receptor/isoquinoline binding protein (PBR/IBP) of human, bovine and murine origin (Genbank accession numbers M36035, M64520 and L17306 respectively). The 170-amino-acid protein of SEQ ID NO: 411 is similar in size and hydrophobicity to known peripheral PBR/IBP benzodiazepine receptors/isoquinoline binding proteins. Like the known peripheral benzodiazepine

receptors/isoquinoline binding proteins, the protein of the subject invention has about five potential transmembrane domains at positions 3-23, 45-65, 82-102, 105-125 and 130-150. Moreover, the protein of the invention displays a stretch of 11 amino acids (starting with V144 and ending with R154) that corresponds to a recently identified putative cholesterol recognition/interaction amino acid consensus pattern (-L/V-(X)(1-5)-Y-(X)(1-5)-R/K-) [See Li *et al*, *Endocrinology* 1998 Dec; 139 (12): 4991-7].

The peripheral benzodiazepine receptor (PBR) is a 18-kDa protein containing binding sites for benzodiazepine and is distinct from the GABA neurotransmitter receptor [Papadopoulos, V. (1993) *Endocr. Rev.* 14: 222-240]. Expression of PBR has been found in every tissue examined. However, it is most abundant in steroidogenic cells and is also found, primarily, on outer mitochondrial membranes [Anholt, R *et al.* (1986) *J. Biol. Chem.* 261:576-583]. PBR is thought to be associated with a multimeric complex composed of the 18-kDa isoquinoline binding protein and the 34-kDa pore-forming voltage dependent anion channel protein, preferentially located on the outer/inner mitochondrial membrane contact sites [McEnery, M.W. *et al. Proc. Natl. Acad. Sci. USA.* 89:3170-3174; Garnier, M. *et al.* (1994) *Mol. Pharmacol.* 45:201-211; Papadopoulos, V. *et al.* (1994) *Mol. Cel. Endocr.* 104:R5-R9]. Drug ligands of PBR, upon binding to the receptor, simulate steroid synthesis in steroidogenic cells in vitro [Papadopoulos, V *et al.* (1990) *J. Biol. Chem.* 265: 3772-3779; Barnea, E. R. *et al.* (1989) *Mol. Cell. Endocr.* 64: 155-159; Amsterdam, A. and Suh, B.S. (1991) *Endocrinology* 128: 503-510]. Likewise, *in vivo* studies showed that high affinity PBR ligands increase steroid plasma levels in hypophysectomized rats [Amri, H. *et al.* (1996) *Endocrinology* 137:5707-5718]. Further in vitro studies on isolated mitochondria provided evidence that PBR ligands, drug ligands, or the endogenous PBR ligand (the polypeptide diazepam-binding inhibitor (DBI) [Papadopoulos, V. *et al.* (1997) *Steroids* 62: 21-28]) stimulate pregnenolone formation by increasing the rate of cholesterol transfer from the outer to the inner mitochondrial membrane [for review, see Culty, M. *et al.* (1999) *Journal of Steroid Biochemistry and Molecular Biology* 69: 123-130].

Based on the amino acid sequence of the 18-kDa PBR, a three dimensional model was developed [Papadopoulos, V. (1996) In: The Leydig Cell. Payne, A. H. *et al.* (eds) Cache River Press, IL, pp 596-628]. This model was shown to accommodate a cholesterol molecule and function as a channel, supporting the role of PBR in cholesterol transport. The role of PBR in steroidogenesis was also demonstrated by observing that PBR negative cells generated by homologous recombination failed to produce steroids [Papadopoulos, V. *et al.* (1997) *J. Biol. Chem.* 272: 32129-32135]. Further, cholesterol transport experiments in bacteria expressing the 18-kDa PBR protein provided definitive evidence for a function as a cholesterol channel/transporter [Papadopoulos, V. *et al.* (1997) *supra*].

In addition to its role in mediating cholesterol movement across membranes, PBR has been implicated in several other physiological functions, including cell growth and differentiation,

chemotaxis, mitochondrial physiology, porphyrin and heme biosynthesis, immune response, anion transport and GABAergic regulation of CNS. [for review, see Gavish, M. *et al.* (1999) *Pharmaceutical Reviews* 51: 629-650; Beurdeley-Thomas, A. *et al.* (2000) *Journal of Neuro-Oncology* 46: 45-56]. Also, a recent report also indicates that PBR agonists are potent anti-apoptotic
5 compounds. These findings suggest that this effect may represent a major function for this receptor (Bono, F. *et al.* (1999) *Biochemical and Biophysical Research Communications* 265:457-461].

It appears that PBR is associated with stress and anxiety disorders. It has been suggested that PBRs play a role in the regulation of several stress systems such as the HPA axis, the sympathetic nervous system, the renin-angiotensin axis, and the neuroendocrine axis. In these
10 systems, acute stress typically leads to increases in PBR density, whereas chronic stress typically leads to decreases in PBR density. Furthermore, in Generalized Anxiety Disorder (GAD), Panic Disorder (PD), Generalized Social Phobia (GSP), and Post-Traumatic Stress Disorders (PTSD), PBR density is typically decreased in platelets.

In the brain, where PBRs are associated with glial cells, PBRs are increased in specific
15 brain areas in neurodegenerative disorders and also after neurotoxic and traumatic-ischemic brain damage [for review, see Gavish, M. *et al.* (1999) *supra*]. The literature also reports a decrease in peripheral-type benzodiazepine receptors in postmortems of chronic schizophrenics, suggesting that the decreased density of PBRs in the brain may be involved in the pathophysiology of schizophrenia. Increased levels of PBR in autopsied brain tissue from PSE patients (Portal-
20 Systemic Encephalopathy patients) have been reported, thus supporting the theory that activation of PBR contributes to the pathogenesis characteristic of portal-systemic encephalopathy (PSE) in the central nervous system [Kurumaji, A. *et al.* (1997) *J. Neural Transm* 104:1361-1370; Butterworth R. F. (2000) *Neurochemistry International* 36: 411-416].

In addition to its involvement in the neurological disorders discussed *supra*, PBR has been
25 implicated in the regulation of tumor cell proliferation [for review, see Gavish, M. *et al.* (1999) *supra*; Beurdeley-Thomas, A. *et al.* (2000) *supra*; Hardwick, M. (1999) *Cancer Research* 59:831-842; Venturini, I. *et al.* (1998) *Life Sci* 63:1269-80; Carmel I *et al.* (1999) *Biochem Pharmacol* 58: 273-8]. The invasiveness and metastatic ability of human breast tumor cells is proportional to the level of PBR expressed. Further, PBR has been proposed to be used as a tool/marker for detection,
30 diagnosis, prognosis and treatment of cancer [WO 99/49316, hereby incorporated by reference in its entirety].

Many ligands have been described that bind to peripheral benzodiazepine receptor with various affinities. Some benzodiazepines, Ro 5-4864 [4-chlorodiazepam], diazepam and structurally related compounds, are potent and selective PBR ligands. Exogenous ligands also include 2-
35 phenylquinoline carboxamides (PK11195 series), imidazo [1,2-a]pyridine-3-acetamides (Alpidem series) and pyridazine derivatives. Some endogenous compounds, including porphyrins and

diazepam binding inhibitor (DBI), bind to PBR with nanomolar and micromolar affinity [for review, see Gavish, M. *et al.* (1999) *supra*; Beurdeley- Thomas, A. *et al.* (2000) *supra*].

The protein of SEQ ID NO: 411 is a novel peripheral-type benzodiazepine receptor. As such, it serves a channel function that mediates cholesterol movement across membranes, play a role in steroidogenesis, cell growth and differentiation, chemotaxis, mitochondrial physiology, protection against apoptosis, porphyrin and heme biosynthesis, immune response, anion transport and GABAergic regulation of CNS.

In one embodiment, a preferred polypeptide of the invention comprises the amino acids of SEQ ID NO: 411 from position 144 to 154. In another embodiment, the subject invention provides a polypeptide comprising the sequence of SEQ ID NO: 411. Other preferred polypeptides of the invention include biologically active fragments of SEQ ID NO: 411. Biologically active fragments of the protein of SEQ ID NO: 411 have any of the biological activities described herein which are associated with the PBR. In another embodiment, the polypeptide of the invention is encoded by clone 181-10-1-0-C9-CS.

One aspect of the subject invention provides compositions and methods using the protein of the invention, or biologically active fragments thereof, for the development, identification, and/or selection of agents capable of modulating the expression or activity of the protein of the invention.

Agents which modulate the activity of the PBR/IBP of the subject invention include, but are not limited to, antisense oligonucleotides, ribozymes, drugs, and antibodies. These agents may be made and used according to methods well known in the art. Also, the protein of the invention, or biologically active fragments thereof, may be used in screening assays for therapeutic compounds. A variety of drug screening techniques may be employed. In this aspect of the invention, the protein or biologically active fragment thereof, may be free in solution, affixed to a solid support, recombinantly expressed on, or chemically attached to, a cell surface, or located intracellularly. The formation of binding complexes, between the protein of the invention, or biologically active fragments thereof, and the compound being tested, may then be measured.

In one embodiment, the subject method utilizes eukaryotic or prokaryotic host cells which are stably transformed with recombinant nucleic acids expressing the PBR/IBP polypeptide or biologically active fragments thereof. The transformed cells may be viable or fixed. Drugs or compounds which are candidates for the modulation of the PBR/IBP, or biologically active fragments thereof, are screened against such transformed cells in binding assays well known to those skilled in the art. Alternatively, assays such as those taught in Geysen H. N., WO Application 84/03564, published on Sep. 13, 1984, and incorporated herein by reference in its entirety, may be used to screen for peptide compounds which demonstrate binding affinity for, or the ability to modulate, the PBR/IBP, or biologically active fragments thereof. In another embodiment, competitive drug screening assays using neutralizing antibodies specifically compete with a test

compound for binding to the PBR/IBP protein of the invention, or biologically active fragments thereof.

Another embodiment of the subject invention provides compositions and methods of selectively modulating the expression or activity of the protein of the invention. Modulation of the PBR/IBP would allow for the successful treatment and/or management of diseases or biochemical abnormalities associated with the PBR or PBR/IBP. Antagonists, able to reduce or inhibit the expression or the activity of the protein of the invention, would be useful in the treatment of diseases associated with elevated levels of the PBR/IBP, increased cell proliferation, or increased cholesterol transport. Thus, the subject invention provides methods for treating a variety of diseases or disorders, including, but not limited to, cancers, especially liver cancer, and portal-systemic encephalopathy.

Alternatively, the subject invention provides methods of treating diseases or disorders associated with decreased levels of the protein of the PBR/IBP. Thus, the subject invention provides methods of treating diseases including, and not limited to, schizophrenia, chronic stress, GAD, PD, GSP and PTSD. Other diseases which may be treated by agonists of the PBR/IBP of the subject invention include those diseases associated with decreases in cell proliferation, e.g. developmental retardation.

Furthermore, because the PBR/IBP of the subject invention is also able to transport cholesterol into cells, the subject invention may also be used to increase cholesterol transport into cells. Diseases associated with cholesterol transport deficiencies include lipoidal adrenal hyperplasia, and diseases where there is a requirement for increased production of compounds requiring cholesterol such as myelin and myelination, such as Alzheimer's disease, spinal cord injury, and brain development neuropathy [Snipes, G. and Suter, U. (1997) Cholesterol and Myelin. In: Subcellular Biochemistry, Robert Bittman (ed.), vol. 28, pp. 173-204, Plenum Press, New York]. The methods of treating disorders associated with decreased levels of PBR/IBP may be practiced by introducing agonists which stimulate the expression or the activity of the protein of the invention.

In one embodiment, methods of increasing the levels of PBR/IBP in tissues or cell types may be practiced by utilizing nucleic acids encoding the protein of the subject invention, or biologically active fragments thereof, to introduce biologically active polypeptide into targeted cell types. Vectors useful in such methods are known to those skilled in the art as are methods of introducing such nucleic acids into target tissues.

Agents which stimulate or inhibit the activity of the protein of the invention include but are not limited to agonist and antagonist drugs respectively. These drugs can be obtained using any of a variety of drug screening techniques as discussed above.

Antagonists of the PBR/IBP encoded by SEQ ID NO: 170 include agents which decrease the levels of expressed mRNA encoding the protein of SEQ ID NO: 411. These include, but are not limited to, RNAi, one or more ribozymes capable of digesting the protein of the invention mRNA,

or antisense oligonucleotides capable of hybridizing to mRNA encoding the PBR/IBP of SEQ ID NO: 411. Antisense oligonucleotides can be administered as DNA, as DNA entrapped in proteoliposomes containing viral envelope receptor proteins [Kanoda, Y. *et al.* (1989) *Science* 243: 375] or as part of a vector which can be expressed in the target cell and provide antisense DNA or RNA. Vectors which are expressed in particular cell types are known in the art. Alternatively, the DNA can be injected along with a carrier. A carrier can be a protein such as a cytokine, for example interleukin 2, or polylysine-glycoprotein carriers. Carrier proteins, vectors, and methods of making and using polylysine carrier systems are known in the art. Alternatively, nucleic acid encoding antisense molecules may be coated onto gold beads and introduced into the skin with, for example, a gene gun [Ulmer, J.B. *et al.* (1993) *Science* 259:1745].

Antibodies, or other polypeptides, capable of reducing or inhibiting the activity of PBR/IBP may be provided as in isolated and substantially purified form. Alternatively, antibodies or other polypeptides capable of inhibiting or reducing the activity of the PBR/IBP protein, may be recombinantly expressed in the target cell to provide a modulating effect. In addition, compounds which inhibit or reduce the activity of the PBR/IBP protein of the subject invention may be incorporated into biodegradable polymers being implanted in the vicinity of where drug delivery is desired. For example, biodegradable polymers may be implanted at the site of a tumor or, alternatively, biodegradable polymers containing antagonists/agonists may be implanted to slowly release the compounds systemically. Biodegradable polymers, and their use, are known to those of skill in the art (see, for example, Brem *et al.* (1991) *J. Neurosurg.* 74:441-446).

In another embodiment, the invention provides methods and compositions for detecting the level of expression of the mRNA of the protein of the invention. Quantification of mRNA levels of the PBR/IBP protein of the invention may be useful for the diagnosis or prognosis of diseases associated with an altered expression of the protein of the invention. Assays for the detection and quantification of the mRNA of the protein of the invention are well known in the art (see, for example, Maniatis, Fritsch and Sambrook, *Molecular Cloning; A Laboratory Manual* (1982), or *Current Protocols in Molecular Biology*, Ausubel, F.M. *et al.* (Eds), Wiley & Sons, Inc.).

Polynucleotide probes or primers for the detection of the mRNA of the protein of SEQ ID NO: 411 can be designed from the cDNA of SEQ ID NO: 170. Methods for designing probes and primers are known in the art. In another embodiment, the subject invention provides diagnostic kits for the detection of the mRNA of the protein of the invention in cells. The kit comprises a package having one or more containers of oligonucleotide primers for detection of the protein of the invention in PCR assays or one or more containers of polynucleotide probes for the detection of the mRNA of the protein of the invention by in situ hybridization or Northern analysis. Kits may, optionally, include containers of various reagents used in various hybridization assays. The kit may also, optionally, contain one or more of the following items: polymerization enzymes, buffers, instructions, controls, or detection labels. Kits may also, optionally, include containers of reagents

mixed together in suitable proportions for performing the hybridization assay methods in accordance with the invention. Reagent containers preferably contain reagents in unit quantities that obviate measuring steps when performing the subject methods.

In another embodiment, the invention relates to methods and compositions for detecting and
5 quantifying the level of the protein of the invention present in a particular biological sample. These methods are useful for the diagnosis or prognosis of diseases associated with an altered levels of the protein of the invention. Diagnostic assays to detect the protein of the invention may comprise a biopsy, in situ assay of cells from organ or tissue sections, or an aspirate of cells from a tumor or normal tissue. In addition, assays may be conducted upon cellular extracts from organs, tissues,
10 cells, urine, or serum or blood or any other body fluid or extract.

Assays for the quantification of the PBR/IBP of SEQ ID NO: 411 may be performed according to methods well known in the art. Typically, these assays comprise contacting the sample with a ligand of the protein of the invention or an antibody (polyclonal or monoclonal) which recognizes the protein of the invention or a fragment thereof, and detecting the complex formed
15 between the protein of the invention present in the sample and the ligand or antibody. Fragments of the ligands and antibodies may also be used in the binding assays, provided these fragments are capable of specifically interacting with the BRP/IRP of the subject invention. Further, the ligands and antibodies which bind to the BRP/IRP of the invention may be labeled according to methods known in the art. Labels which are useful in the subject invention include, but are not limited to,
20 enzymes labels, radioisotopic labels, paramagnetic labels, and chemiluminescent labels. Typical techniques are described by Kennedy, J. H., *et al.* (1976) *Clin. Chim. Acta* 70:1-31; and Schurs, A. H. *et al.* (1977) *Clin. Chim. Acta* 81: 1-40.

The subject invention also provides methods and compositions for the identification of metastatic tumor masses. In this aspect of the invention, the polypeptides and antibodies which
25 bind the polypeptides of the invention may be used as a marker for the identification of the metastatic tumor mass. Metastatic tumors which originated from the liver may overexpress the PBR/IBP of SEQ ID NO: 411, whereas newly forming tumors, or those originating from other tissues are not expected to bear the PBR/IBP of SEQ ID NO: 411.

Protein of SEQ ID NO: 397 (internal designation 160-28-4-0-C4-CS).

30 The protein of SEQ ID NO: 397, encoded by the cDNA of SEQ ID NO: 156 (clone 160-28-4-0-C4-CS), exhibits homology to the ADP-ribosylation factors (ARF) family of proteins. The ARF family includes ADP-ribosylation factors (ARFs) and ARF-like proteins (ARLs); the ARF family of proteins is one family of the Ras superfamily. Proteins belonging to the Ras superfamily have molecular weights of 18-30 kDa and function in a variety of cellular processes including, but
35 not limited to, signaling, growth, immunity, and protein transport.

ARFs are monomeric GTP-binding proteins, related structurally to both G protein alpha-subunits and Ras proteins. ARF family members share more than 60% sequence identity, appear to be ubiquitous in eukaryotes, and are evolutionarily highly conserved throughout. Immunologically, they have been localized to the Golgi apparatus of several types of cells (Stearns et al. Proc. Natl. Acad. Sci. (USA) 87:1238-1242 (1990)). ARF proteins enhance the ADP-ribosyltransferase activity of cholera toxin as an allosteric activator (Noda et al. Biochim. Biophys. Acta 1034: 195-199 (1990)). ARFs have also been shown to act as regulatory molecules, or "switches", for linking two processes (*e.g.*, the process of vesicle fission from a donor compartment and fusion with an acceptor compartment (Rothman, J. E. and Wieland, F. T. Science 272: 227-234 (1996)). ARF family members fall into three classes, classes I-III, according to their size and sequence homology. Class I comprises ARF1, ARF2, and ARF3; Class II comprises ARF4 and ARF5; and Class III comprises ARF6.

The classes occupy different subcellular locations and have been implicated in different transport pathways. Class I ARFs localize to the Golgi where they are involved in the regulation of ER-Golgi and intra-Golgi transport. Class I ARFs are also involved in the recruitment of cytosolic coat proteins to Golgi membranes during the formation of transport vesicles. Class III (*e.g.*, ARF6) localizes to a tubulovesicular compartment, secretory granules, and the plasma membrane, where it is involved in regulated secretion and recycling. Class II ARFs appear to be cytosolic, but their role has not been elucidated. (Radhakrishna, H. and Donaldson, J. G. J. Cell Biol. 139: 49-61(1997)).

ARF function, in general, is regulated by a GDP-GTP cycle. For example, ARF1 is cytosolic in the GDP bound state, but is associated with membranes when in the GTP bound state. A guanine nucleotide exchange factor (GEF) in the donor compartment recruits ARF1 to the membrane. At the membrane, GTP-ARF1 recruits coat proteins, which assemble together into spherical coats, budding off vesicles in the process. After budding, hydrolysis of bound GTP causes ARF1 to dissociate from the membrane. ARF1 dissociation causes the coat to become unstable and dissociate as well. (Rothman, *supra*.)

Members of the ARF multigene family, when expressed as recombinant proteins in *E. coli*, display different phospholipid and detergent requirements (Price, et al. J. Biol. Chem. 267: 17766-17772 (1992)). Some lipids and/or detergents, *e.g.*, SDS, cardiolipin, dimyristoylphosphatidylcholine (DMPC)/cholate, enhance ARF activities (Bobak, et al. Biochemistry 29:855-861 (1990); Noda, et al. Biochim. Biophys. Acta 1034: 195-199 (1990); Tsai, et al. J. Biol. Chem. 263:1768-1772 (1988)). ARFs also activate phospholipase D (PLD), a membrane-bound enzyme implicated as an effector of several growth factors (Boman, A. L. and Kahn, R. A. Trends Biochem. Sci. 20: 147-150 (1995)). PLD1 has been shown to be activated by a variety of G-protein regulators, for example, PKC (protein kinase C) and ADP-ribosylation factor (ARF). PKC and ARFs may regulate G-proteins either individually or together in a synergistic manner. Recently the role of ARFs in microtubules formation has also been demonstrated. ADP-

ribosylation of tubulin almost completely blocked self-assembly of this protein in brain (Terashima M. et al; J.Nutr Sci Vitaminol 45: 393-400 (1999)).

In general, differences in the various ARF sequences are concentrated in the amino-terminal regions and the carboxyl portions of the proteins. Only three of 17 amino acids in the amino termini
5 have shown to be identical among ARFs, and four amino acids in this region of ARFs 1-5 are missing in ARF 6 (Tsuchiya, et al. J. Biol. Chem. 266: 2772-2777 (1991)). It was reported (Kahn, et al. J. Biol. Chem. 267:13039-13046 (1992)) that the amino-terminal regions of ARF proteins form an alpha-helix and that this domain is required for membrane targeting, interaction with lipid, and ARF activity.

10 Schliefer et al., (J. Biol. Chem. 257: 20-23 (1991)) have described a protein distinctly larger than ARF that possessed ARF-like activity. ARF-like proteins, or ARLs, have been found in different species. Some of ARLs appear to lack ADP-ribosyltransferase-enhancing activity; ARLs may differ in GTP-binding requirements and GTPase activity as compared to various ARF isoforms. For example, ARP, a mammalian ARL, is 33-39% identical to members of the ARF
15 family; ARP, however, differs from other ARF family proteins by virtue of its ability to hydrolyze bound GTP in the absence of other proteins. ARP protein, unlike ARFs, is typically associated with plasma membrane instead of the cytosol (Schurmann, A. J. Biol. Chem. 270, 30657-30663 (1995)).

ARF family members have been implicated in several disease processes, such as Lowe's syndrome, an X-linked disorder characterized by congenital cataracts, renal tubular dysfunction and
20 neurological deficits. These disorders may be due to an inability to recruit ARF to the Golgi membrane (Suchy, S. F. et al. Hum. Mol. Genet. 4: 2245-2250 (1995), Londono I. et al. Kidney Int. 55: 1407-1416 (1999)). It has also been suggested that regulation of ARF is also involved in cystic fibrosis, Dent's disease, diabetes, and autosomal dominant polycystic kidney disease (Marshansky, V., et al. Electrophoresis 18: 2661-2676 (1997)).

25 The new human ARF-related protein of SEQ ID NO:397, encoded by clone 160-28-4-0-C4-CS in one embodiment, and the related polynucleotides, provide new compositions which are useful in the diagnosis, treatment, and prevention of secretory, exocytosis, endocytosis and another "sorting disorders."

The subject invention provides a polypeptide comprising the amino acid sequence of SEQ
30 ID NO: 397 or clone 160-28-4-0-C4-CS, or biologically active fragments thereof. The intact protein of interest is 173 amino acids in length, has an ARF family amino acid motif (Pfam), and has ATP/GTP-binding site motif A P-loop (PS00017). The protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS also has chemical and structural similarity with human ARL1 (P40616), ARD-1 (R66033) and ARF6 (GI 178989) (31%, 31% and 27% identity, respectively). The amino acid
35 length of SEQ ID NO: 397 is similar to those of the aforementioned ARFs. Biologically active fragments of SEQ ID NO: 397 have one or more of the biological activities typically associated the full length protein. In one embodiment, the protein is encoded by clone 160-28-4-0-C4-CS

The invention also provides variants of the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS. The variants have at least about 80%, more preferably at least about 90%, and most preferably at least about 95% amino acid sequence identity to the amino acid sequence of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS. Variants according to the subject invention have at least one
5 functional and/or structural characteristic of ARFs. The invention also provides biologically active fragments of the variant proteins.

The invention includes those polynucleotides encoding the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, variants of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, and biologically active fragments of both the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS and variants
10 thereof. As is apparent to those skilled in the art, a variety of different DNA sequences can encode the amino acid sequence of the proteins, variants, and biologically active fragments of said proteins and variants. It is well within the skill of a person trained in the art to create these alternative DNA sequences encoding proteins having the same, or essentially the same, amino acid sequence. These variant DNA sequences are also within the scope of the subject invention. As used herein,
15 reference to "essentially the same" sequence refers to sequences that have amino acid substitutions, deletions, additions, or insertions that do not materially affect biological activity.

The subject invention provides method of treating cytoskeletal, secretory, and inflammatory disorders/conditions comprising the administration of therapeutically effective amounts of a composition comprising the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS. These
20 methods can also be practiced using variants of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, or biologically active fragments of either SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, or variants of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS. Disorders/conditions which can be treated by the subject invention include, but are not limited to, prostate cancer, brain and another tumors, Lowe's syndrome, glomerulonephritis, chronic glomerulonephritis, tubulointerstitial nephritis, inherited X-
25 linked nephrogenic diabetes insipidus, autosomal dominant polycystic kidney disease (ADPKD), herpes gestationis, dermatitis herpetiformis, lupus erythematosus, Crohn's disease, irritable bowel syndrome and Addison's disease; secretory/endocytotic disorders such as cystic fibrosis, glucose-galactose malabsorption syndrome, hypercholesterolemia, hyper- and hypoglycemia, Grave's disease, goiter, and Cushing's disease; conditions associated with abnormal vesicle trafficking,
30 including acquired immunodeficiency syndrome (AIDS); allergies including hay fever, asthma, and urticaria (hives); autoimmune hemolytic anemia; multiple sclerosis; myasthenia gravis; rheumatoid and osteoarthritis; Chediak-Higashi and Sjogren's syndromes; toxic shock syndrome; traumatic tissue damage; viral, bacterial, fungal, helminthic, and protozoal infections.

In another embodiment, a vector capable of expressing the protein of SEQ ID NO: 397 or
35 clone 160-28-4-0-C4-CS, or biologically active fragments thereof, can be administered to a subject to treat or prevent disorders including, but not limited to, those described above. Alternatively, the vector can encode a variant, or biologically active fragment of the variant protein. Multiple vectors

encoding any combination of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, variants, and/or biologically active fragments of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS and/or variants can be administered to a subject.

In a further embodiment, a pharmaceutical composition comprising a substantially purified protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS (and/or biologically active fragments thereof), in conjunction with a suitable pharmaceutical carrier, can be administered to a subject to treat or prevent the above mentioned disorders. Alternatively, a pharmaceutical composition comprising a substantially purified variant protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS (and/or biologically active fragments thereof), in conjunction with a suitable pharmaceutical carrier, can be administered in the aforementioned therapeutic regimens. As would be apparent to the skilled artisan, any therapeutically effective combination of the protein encoded by SEQ ID NO: 397 or clone 160-28-4-0-C4-CS (and/or biologically active fragments thereof) and variants of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS (and/or biologically active fragments thereof), in conjunction with a suitable pharmaceutical carrier can be used in the aforementioned therapeutic regimens.

ARFs are known to be involved in regulated transport of vesicles. Therefore, in another embodiment, the protein of SEQ ID No: 397 or clone 160-28-4-0-C4-CS, variants, and/or biologically active fragments of said proteins and/or variants can be used as a component of drug delivery vehicles such as colloids or liposomes. The protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS, variants, and/or biologically active fragments of said proteins and/or variants can be incorporated into the lipid membranes of liposomes and can serve as specific targeting agents. The methods of design of such drug delivery systems is known by those skilled in the art and can be practiced according to conventional pharmaceutical principles (Smith H.J. Introduction to the principles of drug design and action, 3rd ed. (1998); Chien Y.W. Novel Drug Delivery systems, 2nd ed. (1992); Storm G. et al J.Liposome Res. 4: 641-666 (1994); and Crommelin D.J.A. et al. Adv. Drug Delivery Rev. 17 : 49-60 (1995)).

In another embodiment of the invention, the polynucleotides encoding the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS can be used for therapeutic purposes. Polynucleotides encoding fragments of the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS can also be used in therapeutic regimens. In one aspect, the complement of the polynucleotide encoding the protein of SEQ ID NO.: 397 or clone 160-28-4-0-C4-CS can be used in situations in which it would be desirable to block the transcription of the mRNA. Modifications of gene expression can be obtained by designing complementary sequences or antisense molecules (DNA, RNA, or PNA) to the control, 5', or regulatory regions of the gene encoding the protein of interest. Such technology is now well known in the art, and sense or antisense oligonucleotides or larger fragments can be designed from various locations along the coding or control regions of sequences encoding the

protein of interest. Methods of treatment utilizing antisense technology are also well known to those skilled in the art.

Another embodiment of the invention provides methods of assessing PLD modulation by using ARF properties of the protein of interest.

- 5 In another embodiment, antibodies which specifically bind the protein of SEQ ID NO: 397 or clone 160-28-4-0-C4-CS can be used for the diagnosis of disorders characterized by expression of the protein, or in assays to monitor patients being treated with the protein of interest. Methods of making both polyclonal and monoclonal antibodies are well-known in the art. Diagnostic assays which can be used in this aspect of the invention include, and are not limited to, ELISAs, RIAs, and
- 10 FACS, and are well known in the art. These assays also provide a basis for diagnosing or identifying altered or abnormal levels of SEQ ID NO:397 or the polypeptides encoded by the human cDNA of clone 160-28-4-0-C4-CS expression as compared to normal individuals. These screening methods are, likewise, well known to the skilled artisan.

- In another embodiment of the invention, the protein of interest, its catalytic or immunogenic
- 15 fragments, or oligopeptides thereof can be used for screening libraries of compounds in any of a variety of drug screening techniques. The fragment employed in such screening can be free in solution, affixed to a solid support, recombinantly expressed on, or chemically attached to, a cell surface, or located intracellularly. The formation of binding complexes between the protein of interest and the agent being tested can be measured by methods well known to those skilled in the
- 20 art. Another technique for drug screening provides for high throughput screening of compounds having suitable binding affinity to the protein of interest. (See, *e.g.*, Geysen, et al. (1984) PCT application WO84/03564.)

- In another embodiment of the invention, the polynucleotides encoding the protein of interest can be used for diagnostic purposes. The polynucleotides can be used to detect and quantify gene
- 25 expression in biopsied tissues in which expression of the protein of interest can be correlated with a disease or condition. Such diagnostic assays are well known in the art and can be used to monitor regulation of the protein of interest levels during therapeutic intervention and/or to determine absence, presence, and excess expression of the protein of interest. Examples of such conditions and disorders have been provided supra. The polynucleotide sequences encoding the protein of
- 30 interest can be used, for example, in Southern or Northern analyses, dot blot, or other membrane-based technologies; in PCR technologies; in dipstick, pin, and ELISA assays; and in microarrays utilizing fluids or tissues from patients to detect altered expression of the protein of SEQ ID NO:397 or clone 160-28-4-0-C4-CS. Such qualitative or quantitative methods are well known in the art.

- 35 In further embodiments, oligonucleotides or longer fragments derived from any of the polynucleotide sequences described herein can be used as targets in a microarray. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to

identify genetic variants, mutations, and polymorphisms. This information can be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents. Microarrays can be prepared, used, and analyzed using methods known in the art. (See, e.g., Brennan, T. M. et al. (1995) U.S. Pat. No. 5,474,796; 5 Heller, R. A. et al. (1997) Proc. Natl. Acad. Sci. 94: 2150-2155; and Heller, M. J. et al. (1997) U.S. Pat. No. 5,605,662.)

Another embodiment of the subject invention provides nucleic acid sequences encoding the protein of interest which can be extended utilizing a partial nucleotide sequence and various PCR-based methods. This aspect of the invention provides methods for the detection of upstream 10 sequences, such as promoters and regulatory elements. Methods of practicing this aspect of the invention are also well known in the art.

In other embodiments of the disclosed therapeutic regimens, any of the proteins, variants, biologically active fragments, antibodies, complementary sequences, or vectors of the invention can be administered in combination with other appropriate therapeutic agents. Selection of the 15 appropriate agents for use in combination therapy can be made by one of ordinary skill in the art. The combination of therapeutic agents can act synergistically to effect the treatment or prevention of the various disorders described above. In particular, purified protein can be used to produce antibodies or to screen libraries of pharmaceutical agents to identify those which specifically bind the protein of interest. Neutralizing antibodies especially preferred for therapeutic use.

20 Protein of SEQ ID NO: 287 (internal designation 174-5-3-0-H7-CS)

The protein of SEQ ID NO: 287, encoded by human cDNA of SEQ ID NO: 46 (clone 174-5-3-0-H7-CS), is highly homologous (more than 99% identity in amino acids) to the human protein encoded by the CLN8 gene listed in Genbank under accession number AF123757. The two proteins differ by two conservative amino-acid substations (alanine for valine at position 155 and 25 serine for asparagine at position 225). In addition, the protein encoded by 174-5-3-0-H7-CS contains seven transmembrane domains. These domains are located at amino acids 25-45, 71-91, 100-120, 133-153, 160-180, 205-225, and 228-248 as predicted by the software TopPred II (Claros and von Heijne, *CABIOS applic. Notes*, 10:685-686 (1994)). The protein encoded by SEQ ID NO: 287 also exhibits a signal peptide at positions 1-50 and a retention signal KKRP from positions 30 283 to 286.

CLN8 was identified recently by positional cloning (Ranta et al., Nat Genet. 1999 Oct.;23(2):233-6). CLN8 encodes a 286 amino-acid putative transmembrane protein with no homology to previously known proteins. A naturally-occurring missense mutation in codon 24 (R24G at the border of the first putative transmembrane domain) is the molecular basis for EPMR 35 ("progressive epilepsy with mental retardation", MIM 600143). EPMR, also called Northern Epilepsy, is an autosomal recessive disorder characterized by normal early development, onset of

generalized tonic-clonic seizures between the ages of 5 and 10 years, and subsequent progressive mental retardation. Neuropathological findings have shown that EPMR is a new member of the neuronal ceroid lipofuscinosis (NCL) group of neurodegenerative disorders. The NCLs are a genetically heterogeneous group of progressive neurodegenerative disorders characterized by the accumulation of autofluorescent lipopigment in various tissues. CLN8 is the eighth gene to be linked to the NCL group of neuro-degenerative disorders.

Subsequently, the homologous mouse gene (Cln8) was sequenced (82% nucleotide identity with the human gene) and localized to the region of the mouse genome linked to motor neuron degeneration, mouse *mnd*. *Mnd* is a naturally-occurring mouse mutant with intracellular autofluorescent inclusions similar to those seen in EPMR. A mutation in *mnd* mouse DNA was identified, indicating that *mnd* is a murine ortholog for CLN8 (Ranta et al., Nat Genet. 1999 Oct;23(2):233-6), and that mice containing mutations in Cln8 represent a murine model for NCL disorders.

Recent experimental evidence has confirmed the transmembrane nature of the CLN8 protein (Lonka L et al., Hum Mol Genet. 2000 Jul 1;9(11):1691-7). CLN8 resides in the endoplasmic reticulum (ER) and recycles between the ER and the ER-Golgi intermediate compartment (ERGIC) via a KKXX ER-retrieval motif at its C-terminus (KKRP, amino-acids 283-286). This motif is recognized and bound by COPI, a vesicle-coating protein found in retrograde vesicles delivering cargo from the *cis* Golgi to the ER. The 30kD CLN8 protein is not processed during its maturation (in particular it is not N-glycosylated). The EPMR-associated R24G mutation does not alter cellular localization in humans.

The subject invention provides a polypeptide encoded by SEQ ID NO: 287 and biologically active fragments of said polypeptide. Compositions comprising polypeptides and pharmaceutically acceptable carriers are likewise provided. Preferred polypeptides, and biologically active fragments thereof, have any of the biological activities or domains/motifs described herein and/or contain the amino acids of positions 155 and 225, 283 to 286. In one embodiment, the protein/polypeptide of SEQ ID NO: 287 is encoded by clone 174-5-3-0-H7-CS.

The ER/ERGIC cellular localization of protein of this invention can be used to target compounds to the ER/ERGIC. This targeting can be observed using any of the techniques known to those skilled in the art including those described in (Lonka L et al., Hum Mol Genet. 2000 Jul 1;9(11):1691-7). In this aspect of the invention, the protein of SEQ ID NO: 287, or biologically active fragments thereof can be used to target liposomes, vesicles, or colloids to the ER/ERGIC compartment where active agents can be delivered. Methods of making and using targeted liposomes are well known in the art.

In another embodiment, liposomes comprising the protein of SEQ ID NO: 287 can contain a second targeting agent for the specific selection of a target cell. The second targeting agent can be selected for its ability to specifically target a cell or tissue. Thus, the second targeting agent can be

specific for tumor markers, such as HER2. Alternatively, markers associated with specific cell types can be used (e.g., CD34, CD4, CD8, etc.). In a preferred embodiment, the second targeting agent is an antibody. Active agents include, but are not limited to, chemotherapeutic agents protein cross-linking agents, inhibitors of protein synthesis, anti-bacterial agents (e.g., antibiotics), antiviral
5 agents, and/or anti-parasitic agents. The ability to bind the COPI coatomer can be assayed as described in (Cosson P, Letourneur F, Science. 1994 Mar 18;263(5153):1629-31).

In another embodiment, the present invention provides methods of, and compositions for, identifying specific cellular compartments, such as the ER, ERGIC, and retrograde transport vesicles. This embodiment provides antibodies which specifically bind the protein of SEQ ID
10 NO: 287, or biologically active fragments thereof, which are labeled with detectable markers, such as gold particles, enzymes, radioisotopes, or paramagnetic labels. ER, ERGIC, and retrograde transport vesicles can be identified in samples according to well-known immuno-diagnostic protocols. The antibodies, either monoclonal or polyclonal, can be made according to well-known methods. In a preferred embodiment, the antibodies bind to ER retention signal.

15 In another embodiment, the protein of the invention or part thereof can be used as a reagent for differential identification of the tissue(s) or cell type(s) present in a biological sample and for diagnosis of diseases and conditions, which include, but are not limited to, asthma, pulmonary edema, atherosclerosis, restenosis, stroke potential, thrombosis and hypertension. Similarly, the protein of the invention, or biologically active fragments thereof, and antibodies thereto can provide
20 immunological probes for differential identification of the tissue(s) or cell type(s). In a number of disorders listed above, particularly of the pulmonary and cardiovascular systems, expression of this protein at significantly higher or lower levels can be routinely detected in certain tissues or cell types (e. g., vascular tissues, cancerous and wounded tissues) or bodily fluids (e. g., lymph, serum, plasma, urine, synovial fluid and spinal fluid) or another tissue or cell sample taken from an
25 individual having such a disorder, relative to the standard gene expression level, i.e., the expression level in healthy tissue or bodily fluid from an individual not having the disorder.

Indeed, the 80 first amino-acids of the protein of the invention are identical to two polypeptides claimed in Patent WO 99/35158, hereby incorporated by reference in its entirety (SEQ ID NO:98 and SEQ ID NO:162 corresponding to Geneseq accession numbers Y38413/Y38428 and
30 Y38492) are over-expressed in pulmonary and endothelial tissues.

The tissue distribution in pulmonary and endothelial tissues indicates that the protein product described in WO 99/35158 is useful for the treatment and diagnosis of cardiovascular and respiratory or pulmonary disorders such as asthma, pulmonary edema, pneumonia, atherosclerosis, restenosis, stroke, angina, thrombosis hypertension, inflammation, and wound healing. Those
35 conditions can be diagnosed by determining the amount of the protein of the invention in a sample. Thus, antibodies raised against the protein of SEQ ID NO: 287, or an immunogenic fragment of the

protein can be used in diagnostic, prognostic, or screening assays such as those taught in WO 99/35158.

Protein of SEQ ID No. 270 (internal designation 116-119-3-0-H5-CS)

The protein of SEQ ID NO: 270 encoded by the extended cDNA SEQ ID NO: 29 is
 5 homologous to the human mitochondrial ATP synthase f subunit or ATPK (E.C. 3.6.1.34) (Swissprot accession number P56134) and is overexpressed in fetal kidney.

The protein of SEQ ID NO: 270, composed of 88 amino acid residues, contains 1
 transmembrane segment (position 1 to 55) predicted by the software TopPred II (Claros and von
 Heijne, *CABIOS applic. Notes*, 10 :685-686 (1994). BLAST results show that 100% homology is found
 10 between amino acids 5 to 88 of the protein of the invention and amino acids 10 to 93 of human ATP
 synthase f chain (93 amino acids total), exon 1 of the cDNA SEQ ID NO: 29 making the difference
 between the 2 proteins (the last 3 exons show 100% homology). Thus, the protein of the invention
 represents a new isoform of human mitochondrial ATP synthase f subunit. It is interesting to note that
 the same splice variant is found in bovin, pig and mouse species.

15 The mitochondrial electron transport (or respiratory) chain is a series of enzyme complexes in
 the mitochondrial membrane that is responsible for the transport of electrons from NADH to oxygen
 and the coupling of this oxidation to the synthesis of ATP (oxidative phosphorylation). ATP then
 provides the

primary source of energy for driving a cell's many energy-requiring reactions. ATP synthase
 20 (F₀ F₁ ATPase) is the enzyme complex at the terminus of this chain and serves as a reversible coupling
 device that interconverts the energies of an electrochemical proton gradient across the mitochondrial
 membrane into either the synthesis or hydrolysis of ATP. This gradient is produced by other enzymes
 of the respiratory chain in the course of electron transport from NADH to oxygen. When the cell's
 energy demands are high, electron transport from NADH to oxygen generates an electrochemical
 25 gradient across the mitochondrial membrane. Proton translocation from the outer to the inner side of the
 membrane drives the synthesis of ATP. Under conditions of low energy requirements and when there is
 an excess of ATP present, this electrochemical gradient is reversed and ATP synthase hydrolyzes ATP.
 The energy of hydrolysis is used to pump protons out of the mitochondrial matrix. ATP synthase is,
 therefore, a dual complex, the F₀ portion of which is a transmembrane proton carrier or pump, and the
 30 F₁ portion of which is catalytic and synthesizes or hydrolyzes ATP. Mammalian ATP synthase
 complex consists of sixteen different polypeptides (Walker, J. E. and Collinson, T. R. (1994) *FEBS
 Lett.* 346: 39-43). Six of these polypeptides (subunits alpha, beta, gamma, delta, epsilon, and an ATPase
 inhibitor protein IF₁) comprise the globular catalytic F₁ ATPase portion of the complex, which lies
 outside of the mitochondrial membrane. The remaining ten polypeptides (subunits a, b, c, d, e, f, g, F₆,
 35 OSCP, and A6L) comprise the proton-translocating, membrane spanning F₀ portion of the complex.
 Like other members of the respiratory chain, all but two of the polypeptide subunits of ATP synthase

are nuclear gene products that are imported into the mitochondria. Enzyme complexes similar to mammalian ATP synthase are found in all cell types and in chloroplast and bacterial membranes. This universality indicates the central importance of this enzyme to ATP metabolism. Transcriptional regulation of these nuclear encoded genes appears to be the predominant means for controlling the biogenesis of ATP synthase. Multiple mitochondrial pathologies exist because of the essential role of mitochondrial oxidative phosphorylation in cellular energy production, in the generation of reactive oxygen species and in the initiation of apoptosis (Wallace, Science, 283:1482-1488, 1999). It is now clear that mitochondrial diseases encompass an assemblage of clinical problems commonly involving tissues that have high energy requirements such as heart, muscle and the renal and endocrine systems.

Over the past 11 years, a considerable body of evidence has accumulated implicating defects in the mitochondrial energy-generating pathway, oxidative phosphorylation, in a wide variety of degenerative diseases including myopathy and cardiomyopathy. Most classes of pathogenic mitochondrial DNA mutations affect the heart, in association with a variety of other clinical manifestations that can include skeletal muscle, the central nervous system (including eye), the endocrine system, and the renal system.

Nuclear mutations causing mitochondrial disorders have been described. They are often found in highly conserved subunits. Mitochondrial disorders with nuclear mutations include : myopathies (PEO, MNGIE, congenital muscular dystrophy, carnitine disorders), encephalopathies (Leigh, Infantile, Wilson's disease, Deafness-Dystonia syndrome), other systemic disorders and cardiomyopathies.

The discovery of a new ATP synthase subunit, and polynucleotides encoding it satisfy a need in the art by providing new compositions which are useful for the diagnosis, prevention, and treatment of cancer, myopathies, immune disorders, and neurological disorders.

It is believed that the protein of SEQ ID NO: 270 or part thereof plays a role in cellular respiration, preferably as a mitochondrial ATP synthase subunit. Preferred polypeptides of the invention are fragments of SEQ ID NO: 270 having any of the biological activity described herein.

An object of the present invention are compositions and methods of targeting heterologous compounds, either polypeptides or polynucleotides to mitochondria by recombinantly or chemically fusing a fragment of the protein of the invention to an heterologous polypeptide or polynucleotide. Preferred fragments are signal peptide, amphiphilic alpha helices and/or any other fragments of the protein of the invention, or part thereof, that may contain targeting signals for mitochondria including but not limited to matrix targeting signals as defined in Herrman and Neupert, Curr. Opin Microbiol. 3:210-4 (2000); Bhagwat et al. J. Biol. Chem. 274:24014-22 (1999), Murphy Trends Biotechnol. 15:326-30 (1997); Glaser et al. Plant Mol Biol 38:311-38 (1998); Ciminale et al. Oncogene 18:4505-14 (1999). Such heterologous compounds may be used to modulate mitochondria's activities. For example, they may be used to induce and/or prevent mitochondrial-induced apoptosis or necrosis. In addition, heterologous polynucleotides may be used for mitochondrial gene therapy to replace a defective mitochondrial gene and/or to inhibit the deleterious expression of a mitochondrial gene.

The invention further relates to methods and compositions using the protein of the invention or part thereof to diagnose, prevent and/or treat several disorders in which mitochondrial respiratory electron transport chain is impaired, including but not limited to mitochondriocytopathies, necrosis, aging, myopathies, cancer and neurodegenerative diseases such as Alzheimer's disease, Huntington's disease, Parkinson's disease, epilepsy, Down's syndrome, dementia, multiple sclerosis, and amyotrophic lateral sclerosis. For diagnostic purposes, the expression of the protein of the invention could be investigated using any of the Northern blotting, RT-PCR or immunoblotting methods described herein and compared to the expression in control individuals. For prevention and/or treatment purposes, the protein of the invention may be used to enhance electron transport and increase energy delivery using any of the gene therapy methods described herein or known to those skilled in the art.

In another embodiment, The invention further relates to methods and compositions using the protein of the invention or part thereof to diagnose, prevent and/or treat several disorders in which mitochondrial respiratory electron transport chain needs to be impaired, including but not limited to Sjogren's syndrome, Addison's disease, bronchitis, dermatomyositis, polymyositis, glomerulonephritis, diabetes mellitus, emphysema, Graves' disease, atrophic gastritis, lupus erythematosus, myasthenia gravis, multiple sclerosis, autoimmune thyroiditis, ulcerative colitis, anemia, pancreatitis, scleroderma, rheumatoid and osteoarthritis, asthma, allergic rhinitis, atopic dermatitis, dermatomyositis, polymyositis, and gout, using any techniques known to those skilled in the art including the antisense or triple helices strategies described herein.

Moreover, antibodies to the protein of the invention or part thereof may be used for detection of mitochondria organelles and/or mitochondrial membranes using any techniques known to those skilled in the art.

Protein of SEQ ID NO: 271 (internal designation 117-001-5-0-G3-CS)

The protein of SEQ ID NO: 271 is homologous to the family of lipopolysaccharide (LPS) binding proteins (LBPs). Several families of proteins have the ability to bind LPS including (a) the lipopolysaccharide-binding proteins (LBPs), and (b) the bactericidal permeability-increasing proteins (BPIs). Cholesteryl ester transfer protein (CETP), which is involved in the transfer of insoluble cholesteryl esters in reverse cholesterol transport, shares some homology to members of the LPS binding family of proteins.

Lipopolysaccharide (LPS), alternatively known as bacterial endotoxin, is a major component of the outer membrane of Gram-negative bacteria. It consists of serotype-specific O-side chain polysaccharides linked to a core oligosaccharide and Lipid A. LPS is a potent mediator of the inflammatory response and stimulates the expression of many pro-inflammatory and pro-coagulant compounds in monocytes, macrophages, and endothelial cells. While these responses are important in containing and eliminating localized infections, systemic exposure to LPS can lead to a number of

adverse effects. These include: (a) induction of an inflammatory cascade, (b) damage to the endothelium, (c) widespread coagulopathies, and (d) organ damage.

Systemic exposure to LPS can arise from direct infection by Gram-negative bacteria, leading to the complications of Gram-negative sepsis. Examples of diseases which are associated with Gram-negative bacterial infection or endotoxemia (including bacterial meningitis, neonatal sepsis, cystic fibrosis, inflammatory bowel disease, and liver cirrhosis), Gram-negative pneumonia, Gram-negative abdominal abscess, hemorrhagic shock, and disseminated intravascular coagulation. Subjects who are leukopenic or neutropenic, including subjects treated with chemotherapy or immunocompromised subjects, are particularly susceptible to bacterial infection and the subsequent effects of endotoxin exposure.

Gram-negative sepsis remains one of the primary causes of severe systemic inflammation in hospitalized and immunocompromised patients. Alternatively, changes in gut permeability by a variety of circumstances, including trauma, can lead to translocation of bacteria/LPS into the bloodstream. Bacteria translocated from the gut is thought to play a major role in post-surgical immunosuppression (Little et al., Surgery. 114: 87-91 (1993)) and hemorrhagic shock. Therefore, there is a great interest to characterize proteins involved in the biological response to LPS and to discover therapies that can counteract the effects of LPS in pathological situations.

LBP is a 60 kDa glycoprotein synthesized in the liver and present in normal human serum. LBP expression is upregulated in response to infectious, inflammatory, and toxic mediators. LBP expression has been induced in animals challenged with LPS, silver nitrate, turpentine, and *Corynebacterium parvum* (Geller et al., Surgery 128:22-28 (1993); Gallay et al., Infect. Immun. 61:378-383 (1993); Tobias et al., J. Exp. Med. 164:77-793 (1986)). LBP levels are correlated with exposure to LPS, and elevated levels (particularly persistent elevated levels) have been correlated with poor clinical outcomes in septic patients (U.S. Patent Nos. 5,484,705, and 5,804,367, hereby incorporated by reference in their entirety).

A portion of the LBP molecule (the N-terminal 1-197 aa) binds to the lipid A portion of the LPS molecule to form a high affinity LBP/LPS complex (Tobias, et al., J. Biol. Chem 264: 10867-10871 (1989)). The LBP/LPS complex potentiates the cellular response to LPS via an interaction with the monocytic differentiation antigen CD14 (Wright et al., Science. 249: 1431-1433 (1990); Lee et al., J. Exp. Med. 175:1697-1705 (1992)). LPS can be transferred from LBP to membrane-bound or soluble CD14. Activated CD14 can then interact with endothelial cells to elicit an inflammatory response. The C-terminal portion of LBP is required to transfer LPS to CD14 (U.S. Pat. No. 5,731,415; Theofan et al., J. Immunol. 152:3624-29 (1994); Han et al., J. Biol. Chem. 269:8172-75 (1994)). Evidence also suggests that LBP can neutralize LPS by an interaction with serum lipoproteins or through the internalization of an LBP/LPS/CD14 complex by neutrophils (Wurfel et al., J. Exp. Med. 180:1025-1035 (1994); Wurfel et al., J. Exp. Med. 181:1743-54 (1995); Gegner et al., J. Biol. Chem. 270:5320-5325 (1995)).

The subject invention provides the polypeptide of SEQ ID NO: 271 and polynucleotide sequences encoding the amino acid sequence of SEQ ID NO: 271. In a one embodiment, the polypeptides of SEQ ID NO: 271 are interchanged with the polypeptides encoded by the human cDNA of clone 181-20-3-0-B5-CS. Also included in the invention are biologically active fragments of the protein of SEQ ID NO: 271 and polynucleotide sequences encoding these biologically active fragments. In a preferred embodiment, biologically active fragments of SEQ ID NO: 271 are encoded by clone 181-20-3-0-B5-CS and comprise the first 181 amino acids encoded by clone 181-20-3-0-B5-CS. "Biologically active fragments" are defined as those peptide or polypeptide fragments of SEQ ID NO: 271 which have at least one of the biological functions of the full length protein (e.g., the ability to bind bacterial LPS).

The invention also provides variants of SEQ ID NO: 271. These variants have at least about 80%, more preferably at least about 90%, and most preferably at least about 95% amino acid sequence identity to the amino acid sequence of SEQ ID NO: 271. Variants according to the subject invention also have at least one functional or structural characteristic of SEQ ID NO: 271, such as the biological functions described above. The invention also provides biologically active fragments of the variant proteins. Unless otherwise indicated, the methods disclosed herein can be practiced utilizing the polypeptide of SEQ ID NO: 271 or variants thereof. Likewise, the methods of the subject invention can be practiced using biological fragments of the protein of SEQ ID NO: or variants of said biologically active fragments.

Because of the redundancy of the genetic code, a variety of different DNA sequences can encode SEQ ID NO: 271. It is well within the skill of a person trained in the art to create these alternative DNA sequences which encode proteins having the same, or essentially the same, amino acid sequence. These variant DNA sequences are, thus, within the scope of the subject invention. As used herein, reference to "essentially the same sequence" refers to sequences that have amino acid substitutions, deletions, additions, or insertions that do not materially affect biological activity. Fragments retaining one or more characteristic biological activity of SEQ ID NO: are also included in this definition.

"Recombinant nucleotide variants" are alternate polynucleotides which encode a particular protein. They can be synthesized, for example, by making use of the "redundancy" in the genetic code. Various codon substitutions, such as the silent changes which produce specific restriction sites or codon usage-specific mutations, can be introduced to optimize cloning into a plasmid or viral vector or expression in a particular prokaryotic or eukaryotic host system, respectively.

The protein of SEQ ID NO: 271, and variants thereof, can be used to produce antibodies according to methods well known in the art. The antibodies can be monoclonal or polyclonal. Antibodies can also be synthesized against fragments of SEQ ID NO: 271, as well as variants thereof, according to known methods. The subject invention also provides antibodies which

specifically bind to biologically active fragments of SEQ ID NO: 271 or biologically active fragments of SEQ ID NO: 271 variants.

The subject invention also provides for immunoassays which are used to screen for, monitor, or diagnose exposure to LPS. In one embodiment, diagnostic assays measure the level of LBP in patient plasma samples. LBP levels are known to rise in response to exposure to LPS, thus the measurement of the level of the protein of SEQ ID NO: 271 can provide an early indication of Gram-negative infection or of endotoxin exposure.

The subject invention provides methods of treating individuals infected with Gram negative bacteria comprising the administration of therapeutically-effective compositions comprising SEQ ID NO: 271. In one embodiment, the protein lacks the C-terminal portion (or portions of the C-terminal domain) necessary to transfer LPS to CD14. LPS can be scavenged by the excess N-terminal fragment and would be unable to induce an inflammatory response (see, *e.g.*, U.S. Patent No. 5,731,415, hereby incorporated by reference in its entirety).

Another aspect of the subject invention provides methods of prophylaxis. The method treats individuals by administration of therapeutically-effective amounts of compositions comprising SEQ ID NO: 271. Instances where this aspect of the invention can be performed include, but are not limited to, conditions associated with increased translocation of gut bacteria and endotoxin, particularly prior to surgery. In addition, patients who are at risk for potential Gram-infection, including but not limited to patients undergoing chemotherapy, or patients who are immunocompromised (for example with AIDS) can benefit from such treatment. Such uses are described in U.S. Patent No. 5,990,082, hereby incorporated by reference in its entirety.

The N-terminal portion of LBP, which lacks the ability to induce an inflammatory response, can be fused to other proteins or fragments thereof (such as the bactericidal/permeability-increasing protein or BPI) which can increase the association of these molecules with LPS and aid in the clearance of endotoxin from patients who have been exposed to Gram negative bacteria. Such preparations can be used to treat and inhibit a number of Gram-negative infections, Gram positive, or fungal infections, as described in the following patents: WO 95/19179 A, WO 95/19180 A, WO 95/19372 A, and WO 96/34873 A, each of which is incorporated by reference in its entirety.

The subject invention also provides methods of removing endotoxin from recombinantly-produced proteins. In one embodiment, the recombinantly-produced proteins are obtained from Gram-negative bacteria. In a preferred embodiment, the bacteria are *E. coli*. In another embodiment, the protein of SEQ ID NO: 271, biologically active fragments thereof, variants, or derivatives thereof, are contacted with compositions comprising recombinantly-produced proteins. The contacting step can take place with SEQ ID NO: 271 immobilized on a substrate or with SEQ ID NO: 271 present in free solution.

In addition, protein of SEQ ID NO: 271, biologically active fragments, or derivatives thereof, can be used in diagnostic assays to measure the level of LPS in patient plasma samples. In

such an assay, serum samples would be bound to a solid matrix, such as a membrane, plastic, treated plastic, or other supports, and then cloned with the protein of SEQ ID NO: 271.

Visualization can be achieved by fusing protein of SEQ ID NO: to any number of enzymes followed by treatment with a chromogenic, fluorogenic, or luminescent substrate. Alternatively, the protein of SEQ ID NO: 271, biologically active fragments, variants, or derivatives thereof, can be linked to a fluorescent or luminescent protein or compound. The linkage can be chemical or made by recombinant techniques known to those skilled in the art. In addition, antibodies raised against the protein of SEQ ID NO: 271, biologically active fragments, variants, or derivatives thereof can be used to visualize the LPS/protein 271 complexes using immunoassays known to those skilled in the art.

Protein of SEQ ID NO:266 (internal designation 116-110-2-0-F4-CS)

The protein of SEQ ID NO:266, highly expressed in the testis, is encoded by cDNA of SEQ ID NO:25 and exhibits homology to the Ly-6 family of GPI-linked cell-surface glycoproteins composed of one or more copies of a conserved domain of about 100 amino-acid residues (PS00983; LY6_UPAR).

The protein of SEQ ID NO:266 shows significant structural similarities to mouse Ly-6 antigens, human CD59 and a herpes virus CD59 homolog. The protein of SEQ ID NO:266 displays one copy of the motif of the u-PAR/Ly-6 domain, with all ten extracellular cysteine residues conserved. The mature protein sequence contains a relatively high proportion of cysteine residues (10/105), which suggests that numerous disulfide bonds stabilize its tertiary structure. Furthermore, the 124 amino-acid long protein of SEQ ID NO:266 has a size very similar to that of many members of the Ly-6 family. In addition, the protein of the invention has a predicted signal peptide structure (positions from 1 to 19) and a C-terminal hydrophobic fragment (positions from 101 to 121) necessary for GPI-anchoring in a membrane. Thus, the protein of the invention has a clear evolutionary relationship with the Ly-6/uPAR family, particularly with Ly-6 subfamily.

The Ly-6/uPAR protein family members share one or several repeat units of the Ly-6/uPAR domain, which is defined by a distinct disulfide bonding pattern between 8 or 10 cysteine residues. This family can be divided into two subfamilies. One comprises GPI-anchored glycoprotein receptors with 10 cysteine residues. Another subfamily includes the secreted single-domain snake and frog cytotoxins, and differs significantly in that its members generally possess only eight cysteines and no GPI-anchoring signal sequence (Andermann K, et al. Protein Sci 8(4):810-819 (1999)). The Ly-6 family members are low molecular weight phosphatidyl inositol anchored glycoproteins with remarkable amino acid homology throughout a distinctive cysteine rich protein domain that is associated predominantly with O-linked carbohydrate. Their GPI links are necessary to anchor these cell surface proteins to the outside of the lipid bilayer membrane. The Ly-6 family includes human CD59, which protects from complement-mediated membrane damage, squid Sgp1

and Sgp2, urokinase plasminogen activator receptor, murine Sca-1 and Sca-2, and many other proteins. The general structure seen within the Ly-6 family resembles that of the receptor for a urokinase-type plasminogen activator and the alpha- neurotoxins from snake venoms (Fleming T J et al J Immunol 150:5379-5390 (1993); Ploug M and V Ellis FEBS Lett 349:163-168 (1994)).

5 The Ly-6 cell surface proteins are differentially expressed in several hematopoietic lineages that appear to function in signal transduction and cell activation predominantly on lymphoid cells in the mouse. Analyses using anti-Ly-6A/E monoclonal antibodies has also demonstrated in situ expression of Ly-6 molecules in brain tissue (staining primary associated with vascular elements throughout the brain). These proteins do not appear to be expressed during embryonic or neonatal
10 stages of development (Cray C et al. Brain Res Mol Brain Res 8(1):9-15 (1990)).

 Ly-6 protein expression has been shown to be factor-dependent. For example, the expression of the Ly-6A/E, which normally occurs in hemopoietic stem cells, fibroblasts, and T and B lymphocytes, has been shown to be greatly induced by IFN- β in various tissues and cell lines. In addition, the Ly-6E Ag is associated with tyrosine kinases in T cells, and reduced expression of Ly-
15 6E in T cells impairs normal functional responses, as well as tyrosine kinase activity, in these cells. Further, the IFNs are important in the generation of memory CD8+ T cells, and it has been demonstrated that the expression of Ly-6C Ag is a strong marker for the memory phenotype (Mehran M. et al. Journal of Immunology 163: 811-819 (1999)). Like their murine counterparts, a human homologue of Ly-6 genes, the 9804 gene, is responsive to IFNs. The 9804 gene is also
20 inducible by retinoic acid during differentiation of acute promyelocytic leukemia cells. Further, cultured glial and neuronal cells express high levels of Ly-6A/E following incubation with cytokines, including rIFN-gamma. (Cray C et al. Brain Res Mol Brain Res 8(1):9-15 (1990)). Another member of the Ly-6 family, human protein RoBo-1, shows increased expression in response to two modulators of bone metabolism, estradiol and intermittent mechanical loading,
25 suggesting a role in bone homeostasis (Noel LS et al. J Biol Chem, Vol. 273(7): 3878-3883 (1998)). Such factor-dependence of expression makes Ly-6 proteins either candidates or targets for alloresponses and autoimmune disease. For example, the high level factor-induced expression of LY-6s has been associated with lupus nephritis (Blake P G et al. J Am Soc Nephrol 4:1140-1150 (1993)).

30 Murine Ly-6 molecules have interesting patterns of tissue expression during haematopoiesis, from multipotential stem cells to lineage committed precursor cells, and on specific leukocyte subpopulations in the peripheral lymphoid tissues. These patterns suggest an intimate association between the regulation of Ly-6 expression, and the development and homeostasis of the immune system (Gumley TP et al. Immunol Cell Biol 73(4):277-296 (1995)). Ly-6M messenger
35 RNA (mRNA) is easily detectable in hematopoietic tissue (bone marrow, spleen, thymus, peritoneal macrophages) as well as kidney and lung (Patterson JM et al. Blood 95(10):3125-3132 (2000)).

Normally, human blood cells are protected against autologous complement activation by membrane proteins that block the assembly of functional complement pores. One such protein is human Ly-6 CD59. Administration of CD59 prevents hemolytic disease or thrombosis. Further, the CD59 protein may prevent the complement-mediated lysis and activation of endothelial cells
5 that leads to hyper acute rejection, and therefore may be administered during xenogeneic organ transplantation (Binette, J. P. and Binette, M. B., *Scanning Microsc.*, 7:1107-10 (1993)).

The surface receptor for urokinase plasminogen activator (uPAR) has been recognized in recent years as a key molecule in regulating plasminogen mediated extracellular proteolysis. Surface plasminogen activation controls the connections between cells, basement membrane and
10 extracellular matrix, and therefore the capacity of cells to migrate and invade neighboring tissues (Roldan AL et al. *EMBO J* 9(2):467-474 (1990)). Certain factors of the PA system, such as u-PAR, have been detected in organs of the male reproductive tract in various species. The morphological study provide support for the involvement of the PA system in human male reproductive physiology (Gunnarsson M et al. *Mol Hum Reprod* 5(10):934-940 (1999)).

15 LY-6 proteins have been suggested to play important roles in disorders such as cancers, nephropathies, autoimmune diseases, hemolytic disease, thrombosis, Alzheimer's disease, etc. Several members of the murine Ly-6 supergene family are clearly involved in the progression of certain mouse tumors, as their expression level is higher in highly malignant cells than in tumor cells with a lower malignancy phenotype. Sorting by flow cytometry of tumor cells to
20 subpopulations expressing either high or low levels of Ly-6E.1 yielded cells expressing a high or a low malignancy phenotype, respectively. Further, it was shown that LY-6 is highly expressed on non-lymphoid tumor cells originating from a variety of tissues in mice. Upregulation or high expression is correlated with a more malignant phenotype which results in higher efficiency of local tumor production (Katz et al *Int J Cancer* 59:684-91 (1994)) .

25 Cells derived from angiogenic tumors express a higher tumorigenicity phenotype and a higher capacity to produce artificial pulmonary metastases than cells from the poorly angiogenic tumors. These cells also express significantly higher levels of the lymphocyte activation protein Ly-6E, so the angiogenic phenotype appears to be coregulated with Ly-6 (Sagi-Assif O et al. *Immunol Lett* 54(2-3):207-13 (1996)). Some LY-6 proteins also block secretion of interleukin II
30 (IL-2) which is an approved anticancer agent and a key regulatory hormone in cell-mediated immunity (Fleming T J and T R Malek *J Immunol* 153:1955-62 (1994)). IL-2 stimulates the proliferation of both T and natural killer cells and activates NK cells which can directly lyse freshly isolated, solid tumor cells.

The high malignancy, high Ly-6E.1-expressing cells also expressed high levels of the
35 receptor for urokinase plasminogen activator (uPAR), whereas low malignancy, low Ly-6E.1-expressing cells also expressed low levels of uPAR. Transfection studies have indicated that uPAR is causally involved in conferring a high malignancy phenotype upon tumor cells expressing high

levels of Ly-6E.1. E48, a human homologue of the murine ThB Ly-6 protein, is expressed on head and neck squamous carcinoma cells. In E48-stimulated cells, the binding of E48 to its microenvironmental ligand appears to transduce a signal that up-regulates the expression of the FX enzyme in these cells, leading to an increase in the levels of GDP-L-fucose (Rinat Eshel et al. J Biol Chem, Vol. 275(17):12833-12840 (2000)). A congenital disorder of leukocyte adhesion to vascular endothelium termed LADII is reflected in a generalized fucose deficiency and major defects in leukocyte trafficking and function. Ly-6 loss-variants of a murine tumor exhibit alterations in the incorporation of fucose and mannose into cellular glycoconjugates (Witz IP J. Cell. Biochem. Suppl. 34:61-66 (2000)).

10 It is believed that the protein of SEQ ID NO:266 is a novel member of the Ly-6 protein family, and is thus a specific cell-surface glycoprotein antigen involved in signal transduction and cell activation, proliferation and differentiation. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:266 from position 1 to position 18 and from position 19 to position 124. Other preferred polypeptides of the invention are any fragments
15 of SEQ ID NO:266 having any of the biological activities described herein.

In one embodiment, this invention relates to methods and compositions using the protein of the invention or part thereof as a marker protein to selectively identify tissues, preferably testis. For example, the protein of the invention or part may be used to synthesize specific antibodies using any technique known to those skilled in the art. Such tissue-specific antibodies may then be used to
20 identify tissues of unknown origin, such as forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, etc., or to differentiate different tissue types in a tissue cross-section using immunochemistry.

Another embodiment of the present invention relates to methods of using of the protein of the invention or part thereof and related compounds and derivatives to diagnose developmental and
25 malignant disorders in tissues including urogenital tissues and other tissues of the reproduction system of both sexes. For example, a biological sample is obtained from a patient with cancer or at risk of developing cancer, and the level of SEQ ID NO:25 polynucleotides or encoded polypeptides is detected within the cells of the sample. The detection of an elevated level of the SEQ ID NO:25 polynucleotides or encoded polypeptides in the sample relative to a control level indicates the
30 presence of malignant cells within the patient. The expression of the protein of the invention can be investigated using any of a number of methods, including, but not limited to, Northern blotting, RT-PCR or immunoblotting.

Another embodiment of the invention relates to compositions and methods using the protein of the invention or part thereof in recombinant protein form as pharmacological agents in the
35 treatment of developmental and malignant disorders in tissues including urogenital tissues and in other tissues of human reproduction system. Particularly, the protein of the invention or part thereof can be used in the treatment of disorders which are manifested by male sterility.

In another embodiment of the invention, antibodies which bind to the protein of the invention or part thereof are used in the treatment of tumors, e.g., human urogenital tumors, especially to enhance the secretion of interleukin II, which is an approved anticancer agent and key regulatory hormone in cell-mediated immunity. Such antibodies can be used alone or bound to a substance capable of ablating or killing cells as a therapy for urogenital disorders or cancers in which the protein of the invention is overexpressed.

The protein of the invention or part thereof may also be used in the treatment of diseases which can require transplantation, including various forms of cancers such as genitourinary cancers, carcinomas, sarcomas, atherosclerosis, angiogenesis, and benign tumors. As mentioned above, Lys-6 family includes several proteins which are similar to the protein of the invention and which are capable of protecting cells from complement-mediated membrane damage. Therefore, in another embodiment of the invention, recombinant proteins encoded by SEQ ID NO:25 or fragments thereof are administered during xenogeneic tissue transplantation to prevent complement-mediated lysis and to block activation of endothelial cells, which normally leads to hyper-acute rejection.

In addition, prevention of complement-mediated lysis may be particularly important in human and animal reproductive therapy, where functional survival of the germ cells during in vitro handling is crucial. Storage of sperm is of widespread importance in commercial animal breeding programs, human sperm donor programs, and in the treatment of certain disease states. For example, sperm samples may be frozen for men who have been diagnosed with cancer or other diseases that may eventually interfere with sperm production, as well as for assisted reproduction purposes where sperm may be stored for use at other locations or times. The procedures utilized in such cases include: washing a sperm sample to separate out the sperm-rich fraction from non-sperm components of a sample such as seminal plasma or debris; further isolating the healthy, motile sperm from dead sperm or from white blood cells in an ejaculate; freezing or refrigerating of sperm for use at a later date or for shipping to females at differing locations; extending or diluting sperm for culture in diagnostic testing or for use in therapeutic interventions such as in vitro fertilization or intracytoplasmic sperm injection (Cohen et al. 12 : 994-1001 (1997)). Once sperm have been washed or isolated, they are then extended (or diluted) in culture or holding media for a variety of uses (sperm analysis, diagnostic tests, assisted reproduction). Each of these uses for extended or diluted sperm requires a somewhat different formulation of basal medium (see, for review, US Patent No. 6,140,121 Ellington et al. Oct. 2000); however, in all cases sperm survival is suboptimal outside of the female reproductive tract. Novel additional components of a dilution or storage medium which could improve the functional preservation of sperm would be useful. Therefore, in another preferred embodiment of this invention, purified recombinant proteins encoded by SEQ ID NO:25 or fragments thereof can be added as components of pharmacological media designed to protect spermatozoa. The methods used to compose such preservation media are generally known by those skilled in the art (for ex., Oliver S.A. et al. US patent 5,897,987 Apr.1999; Cohen J. et al.,

supra). Inversely, in yet another embodiment of this invention, ligands, inhibitors, neutralizing antibodies or other biological agents which recognize the protein of the invention and which bind it and which block it can be used as components of pharmacological formulations designed for male contraception purposes.

5 In still another embodiment of this invention, chimeric ligands or derivatives which recognize the protein of the invention or part thereof and which could be internalized into cell can be used to design a system of drug delivery finely targeted toward urogenital and other tissues which express the protein of SEQ ID NO:266. For example, such recognizing molecules can be incorporated into the membranes of liposomes to allow the specific delivery of the liposomes to
10 cells expressing the protein of SEQ ID NO:266. Methods of designing such drug delivery systems are known by those skilled in the art (Smith H.J. Introduction to the principles of drug design and action, 3rd ed. (1998)).

Proteins SEQ ID NOs:417, 413, 418 (internal designations 188-45-1-0-D3-CS, 188-26-4-0-F5-CS, and 188-5-1-0-H6-CS)

15 The proteins of SEQ ID NOs:417, 413, and 418, encoded by the cDNAs of SEQ ID NOs: 176, 172, and 177, are expressed in the brain and exhibit strong homology with proteins with redox activity (see, e.g. Genbank accession numbers AK001293 and AF029689, and Geneseq accession number: Y59180).

The protein of SEQ ID No:418 (320 amino acids) is a variant of AK001293 (322 amino
20 acids). AK001293 has six extra nucleotides, within the same ORF, as SEQ ID No:418, producing a longer protein. SEQ ID NO:418 exhibits the Pfam Zinc-binding dehydrogenase (adh zinc) signature from positions 16 to 313. SEQ ID NO:418 presents all the conserved residues of the motif except for a histidine that is thought to be a zinc-ligand. This lack of zinc-ligand residues is a feature of the quinone oxidoreductases (QOR), a subfamily of zinc-binding dehydrogenases.

25 SEQ ID NO:413 (191 amino acids) shares the first 172 amino acids with SEQ ID NO:418. The deletion of one nucleotide at position 583 in the SEQ ID NO:413 cDNA sequence (corresponding to amino acid 173), however, creates a change of ORF compared to SEQ ID NO:418 and AK001293.

SEQ ID NO:417 is a short protein (20 amino acids) whose sequence corresponds to the N-
30 terminal end of the other proteins of the invention. The presence of a T (instead of a G in public sequences and SEQ ID NOs:413 and 418) at position 128 on the cDNA creates a STOP codon, creating a shorter protein.

SEQ ID NOs:417, 413 and 418 are similar to the QORs, a family of zinc-binding
dehydrogenases. QORs are cytoplasmic redox-regulated flavoenzymes that catalyze the one or two-
35 electron reduction of quinones. QORs bind NADP and are inhibited by dicoumarol.

The activity of QORs protects cells against toxicity, mutagenicity, and cancer due to exposure to environmental and synthetic quinones and their precursors. Thus, QORs play a central role in monitoring cellular redox state and act to protect against oxidative stress induced by a variety of metabolic situations (Raina A.K. et al. (1999) Redox Rep. 4:23-7). The oxidoreductase activity also permits the activation of bioreductive anticancer drugs (Begleiter A. et al. (1996) Br. J. Cancer Suppl. 27:S9-14).

The metabolism of quinones involves enzymatic reduction of the quinone by one or two electrons. In the activation of quinone-containing antitumor agents, this reduction results in the formation of the semiquinone or the hydroquinone of the anticancer drug. The consequence of these enzymatic reductions is that the semiquinone yields its extra electron to oxygen with the formation of superoxide radical anion and the original quinone. This reduction by a reductase followed by oxidation by molecular oxygen (dioxygen) is known as redox-cycling and continues until the system becomes anaerobic. In the case of a two-electron reduction, the hydroquinone could become stable, and as such, be excreted by the organism in a detoxification pathway.

The cellular antioxidant response is mediated by a battery of detoxifying/defensive proteins. The promoters of genes that encode these proteins contain a common cis-element termed the antioxidant response element (ARE). Many transcription factors, including Nrf, Jun, Fos, Fra, Maf, YABP, ARE-BP1, Ah (aromatic hydrocarbon) receptor, and estrogen receptor bind to the ARE from various genes. Among these factors, Nrf-Jun heterodimers positively regulate ARE-mediated expression and induction of genes in response to antioxidants and xenobiotics (reviewed in Dhakshinamoorthy S. et al. (2000) Curr. Top Cell Regul. 36:201-16). On the other hand, c-Fos represses ARE-mediated gene expression (Venugopal, R., and Jaiswal, A.K. (1996) Proc. Natl. Acad. Sci. USA 93, 14960-5).

Elevated levels of QOR activity have been reported in several kinds of tumors such as liver, colon, lung and breast (Belinsky M., Jaiswal A.K., (1993) Cancer Metastasis Rev 12:103-17). Bioreactive antitumor agents are an important class of anticancer drugs that require activation by reduction. For this reason, QORs are a potential target on which to base the development of new antitumor compounds. Certain QORs have already been implicated in the metabolism, activation and mechanism of cytotoxicity of some anticancer drugs such as mitomycin C, indoloquinone E09 (Ross D. et al. (1994) Oncol. Res. 6:493-500), CB 1954 (Knox R.J. et al. (2000) Cancer Res. 60:4179-86) or antiestrogens in breast cancer (Montano M.M., Katzenellenbogen B.S. (1997) PNAS 94:2581-6).

In addition, some of the proteins of the QOR family are thought to play a role in the prevention of apoptosis following oxidative stress. The tumor suppressor gene p53 has been directly implicated in the induction of apoptosis in dividing cells and in hippocampal pyramidal neurons (Jordan J. et al. (1997) J. Neurosci 17:1397-405) and a QOR gene has been described as a p53-regulated gene (Kostic C, Shaw P.H. (2000) Oncogene 19:3978-87).

It is believed that the proteins of SEQ ID NOs:417, 413 and 418 have a redox activity, most likely as QORs. Thus, they are expected to act as an endogenous antioxidant against oxidative stress and may be able to use NADP as cofactor. The proteins of the invention may be used to deactivate toxins and to activate bioreductive anticancer drugs. In addition, they may prevent apoptosis following oxidative stress and be regulated by p53. Because proteins SEQ ID NOs:417 and 413 do not contain the Pfam Zinc-binding dehydrogenase (adh zinc) signature, in contrast to SEQ ID NO:418, they may act as a competitive inhibitor, i.e. a dominant negative form, of the functional protein.

The oxidoreductase activity of the proteins of the invention may be assayed using any technique known to those skilled in the art. For example, the measurement of the rate of oxidation of NADPH and oxygen consumption, and the detection of the semiquinone and reactive oxygen species, may be performed as described by Gutierrez P.L. (Gutierrez P.L. (2000) *Front. Biosci.* 5:D629-38), or by any other method skilled in the art. The enzymatic activity of the proteins of the invention in different affected and control tissues may be assayed by histochemical staining. To confirm the role of the proteins of the invention in the cellular antioxidant response, in vitro and in vivo assays may be performed. Transcription levels of the genes coding for the proteins of the invention may be measured using standard techniques after exposure to quinones or derived compounds as beta-naphthoflavone (beta-NF), as described by Belinsky M. and Jaiswal A.K. (supra), as well as in response to transcription factors such as Nrf, Jun and c-Fos, or in the presence of p53.

In one embodiment of the present invention, the present protein can be used to detect specific cell types in vitro or in vivo. For example, as the present proteins are overexpressed in the brain, reagents capable of specifically recognizing the present protein can be used as markers for brain cells. Brain-specific markers have a number of uses, including for the identification of specific tissues for histological analyses, as well as to detect the origin of tumor cells. In addition, as the expression of the present protein is likely induced by transcription factors such as Nrf, Jun, Fos, Fra, Maf, YABP, ARE-BP1, Ah (aromatic hydrocarbon) receptor, and estrogen receptor, as well as by p53, reagents specific for detecting the present protein can also be used as a marker for the activity of any of these proteins in vitro or in vivo. In view of the association between many of these proteins and diseases such as cancer, the ability to detect the presence or absence of the proteins provides powerful tools for disease diagnosis and screening. For any of these applications, the expression of the present protein can be detected using any standard method, including Northern blots, western blots, in situ hybridization, PCR, etc.

In another embodiment, the proteins of the invention can serve as markers for cellular oxidative stress in vivo and in vitro. As such, the proteins of the invention or part thereof may be useful in the diagnosis of disorders in which oxidative stress is implicated, including a large variety of types of cancer as well as neurodegenerative disorders such as Alzheimer's disease (AD), amyotrophic lateral sclerosis (ALS) or Parkinson disease (PD). For diagnostic purposes, the

expression of the protein of the invention may be investigated using, e.g. Northern blotting, RT-PCR or immunoblotting methods and compared to the expression in control individuals. An increased levels of the proteins of the invention in patients compared with controls indicates a major shift in redox balance and, thus, indicates the presence of the disease or of a susceptibility for the
5 disease.

The invention further relates to methods and compositions using the proteins of the invention or part thereof to prevent and/or treat disorders in which oxidative stress is implicated, including those mentioned above. For these purposes the proteins themselves, or polynucleotides encoding the proteins, or an activator of protein expression may be administrated to patients, or to
10 disease-free individuals in case of increased susceptibility to one of these disorders.

In another embodiment, the protein of the invention or part thereof is used to prevent cells from undergoing apoptosis. They may thus be useful in the diagnosis, treatment and/or prevention of disorders and processes in which apoptosis is deleterious, including but not limited to immune deficiency syndromes (including AIDS), type I diabetes, pathogenic infections, cardiovascular and
15 neurological injury, alopecia, aging, degenerative diseases including AD and PD, dystonia, Leber's hereditary optic neuropathy and schizophrenia. For all such diagnostic purposes, the expression of the proteins of the invention can be investigated using any of the Northern blotting, RT-PCR or immunoblotting methods described herein and compared to the expression in control individuals.

The invention relates to methods and compositions using the proteins of the invention or
20 part thereof as detoxifying enzymes against quinones. There are a variety of quinones with a toxic effect in cells (e.g. quinones derived from the oxidation of phenolic metabolites of benzene, DA-quinones, or menadione). Thus, the proteins of the invention or part thereof may be protective against the hematotoxic and carcinogenic effects of benzene, as well as against benzene-caused diseases such as cancer, aplastic anemia and pancytopenia. Moreover, they may detoxify DA-
25 quinones in the brain, thereby providing neuroprotection in Parkinson's Disease. In still another embodiment, the proteins of the invention or part thereof may protect cells against menadione-induced oxidative stress, with known effects on myocardial cells (Floreani M. et al (2000) Biochem Pharmacol. 60:601-5). For prevention and/or treatment purposes the proteins themselves, or polynucleotides encoding the proteins, or an activator of protein expression may be administrated.

30 In another embodiment, the present proteins may be a target of chemotherapy specific to different kinds of cancer, to ensure a favorable response to anticancer drugs. Specifically, proteins of the invention or part thereof may be used as an activator of cytotoxic prodrugs of quinone family. Accordingly, the protein of the invention or part thereof may be administered to a patient in conjunction with a bioreductive anticancer agent in order to activate the drug. This co-
35 administration may be by simultaneous administration, such as a mixture of the oxidoreductase and the drug, or by separate simultaneous or sequential administration. Cancer-specific antitumor agents based on QOR substrates may be designed as described by Xing J. et al. (Xing J. et al. (2000)

Med. Chem. 43:457-66) and assayed as described in Li B. et al. (Li B et al. (1999) Chem. Res. Toxicol. 12:1042-9). Alternatively, as the present proteins may be overexpressed in tumor cells, such methods may be performed by simply detecting the level of the present protein in tumor cells, and administering the prodrug specifically to those patients found to have elevated levels of the
5 protein in their tumor cells.

Proteins of SEQ ID NOs: 415, 310, 317 (internal designation 188-29-2-0-H1-CS, 188-18-4-0-A9-CS, 188-9-2-0-E1-CS)

Mammalian inositol hexakiphosphate kinase 2 (IP6K2), an enzyme of the inositol phosphate pathway, has been cloned and described by two independent groups [Saiardi, A.;
10 Erdument-Bromage, H.; Snowman, A. M.; Tempst, P.; and Snyder, S. H., (1999) Current Biology 9, 1323-1326, and Katai, K.; Miyamoto, K-I.; Kishida, S.; Segawa, H.; Nii, T.; Tanaka, H.; Tani, Y.; Arai, H.; Tatsumi, S.; Morita, K.; Taketani, Y.; and Takeda, E. (1999) Biochem. J. 343, 705-712]. Newly identified consensus sequences of inositol-polypophosphate kinases are represented by [LV]-[LA]-[DE]-X(3-8)-P-X-[VAI]-[ML]-D-X-K-[ML]G [Saiardi, A.; Erdument-Bromage, H.;
15 Snowman, A. M.; Tempst, P.; and Snyder, S. H. (1999) Current Biology 9, 1323-1326]. IP6K2 catalyzes the transfer of phosphate groups from InsP6 or Ins(1,3,4,5,6)P5 (the substrate), to another protein or small molecule, such as a nucleoside di-phosphate.

The subject invention provides the polypeptides of SEQ ID NOs:415, 310, and 317, encoded by the cDNAs of SEQ ID NOs:174, 69, and 76, respectively. The invention also provides
20 biologically active fragments of SEQ ID NOs:415, 310, and 317. In one embodiment, the polypeptides of SEQ ID NOs:415, 310, and 317 are interchanged with the corresponding polypeptides encoded by the human cDNA of clone 188-29-2-0-H1-CS, 188-18-4-0-A9-CS, or 188-9-2-0-E1-CS. "Biologically active fragments" are defined as those peptide or polypeptide fragments having at least one of the biological functions of the full length protein (e.g., kinase
25 activity). Compositions of the protein/polypeptide of SEQ ID NOs:415, 310, or 317, or biologically active fragments thereof, are also provided by the subject invention. These compositions may be made according to methods well known in the art.

The invention also provides variants of the protein of SEQ ID NOs:415, 310, or 317. These variants have at least about 80%, more preferably at least about 90%, and most preferably at least
30 about 95% amino acid sequence identity to the amino acid sequences encoded by SEQ ID NOs:415, 310, and 317. Variants according to the subject invention also have at least one functional or structural characteristic of the protein of SEQ ID NOs:415, 310, or 317. The invention also provides biologically active fragments of the variant proteins. Compositions of variants, or biologically active fragments thereof, are also provided by the subject invention. These
35 compositions may be made according to methods well known in the art. Unless otherwise indicated, the methods disclosed herein can be practiced utilizing the protein encoded by SEQ ID

NO:415, 310, or 317, biologically active fragments of SEQ ID NO:415, 310, or 317, variants of SEQ ID NO:415, 310, or 317, and biologically active fragments of the variants.

Because of the redundancy of the genetic code, a variety of different DNA sequences can encode the amino acid sequence of SEQ ID NO:415, 310, or 317. In a preferred embodiment, SEQ ID NO:415, 310, or 317 is encoded by clone 188-29-2-0-H1-CS, 188-18-4-0-A9-CS, or 188-9-2-0-E1-CS, or by the cDNAs of SEQ ID NO:174, 69, or 76. It is well within the skill of a person trained in the art to create these alternative DNA sequences which encode proteins having the same, or essentially the same, amino acid sequence. These variant DNA sequences are, thus, within the scope of the subject invention. As used herein, reference to “essentially the same” sequence refers to sequences that have amino acid substitutions, deletions, additions, or insertions that do not materially affect biological activity. Fragments retaining one or more characteristic biological activity of the protein encoded by SEQ ID NO:415, 310, or 317 are also included in this definition.

In one aspect of the subject invention, SEQ ID NO:415, 310, or 317, and variants thereof, can be used to generate polyclonal or monoclonal antibodies. Both biologically active and immunogenic fragments of SEQ ID NO:415, 310, or 317, or variant proteins, can be used to produce antibodies. Polyclonal and/or monoclonal antibodies can be made according to methods well known to the skilled artisan. Antibodies produced in accordance with the subject invention can be used in a variety of detection assays known to those skilled in the art. The antibodies may be used to agonize or antagonize the biological activity of the protein of SEQ ID NO:415, 310, or 317.

The protein of SEQ ID NO:415, 310, or 317 can be used for the synthesis of nucleoside triphosphate (NTP) compounds. In one embodiment, the NTP compound produced is ATP, GTP, CTP, or TTP. In this aspect of the subject invention, SEQ ID NO:415, 310, or 317 removes a phosphate from InsP6 or Ins(1,3,4,5,6)P5 and transfers it to a nucleoside diphosphate (e.g., ADP, CTP, GDP, or TDP) to create a NTP. The conditions and methods for the synthesis of NTP compounds, such as ATP, are well known to the skilled artisan. Thus, the protein of SEQ ID NO:415, 310, or 317 has industrially useful function for the synthesis of commercially valuable products.

The subject invention also provides methods of determining the relative amounts of InsP6 or Ins(1,3,4,5,6)P5 in the cell by a kinase assay. In this aspect of the invention, SEQ ID NO:415, 310, or 317 can be used to transfer phosphate groups from InsP6 or Ins(1,3,4,5,6)P5 to acceptor substrates according to well-known kinase activity assays.

Protein of SEQ ID NO:294 (internal designation 181-16-2-0-A7-CS)

The protein of SEQ ID NO:294 is encoded by the cDNA of SEQ ID NO:53. It will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:294 described throughout the present application also pertain to the polypeptide encoded by the human cDNA of clone 181-16-2-0-A7-CS. In addition, it will be appreciated that all characteristics and uses of the

nucleic acid of SEQ ID NO:53 described throughout the present application also pertain to the human cDNA of clone 181-16-2-0-A7-CS.

This gene was isolated from fetal liver and expression has also been detected in fetal kidney, placenta, liver, brain, hypertrophic prostate, salivary gland and testis. Data from PCT application WO 98/23435 indicate expression is primarily in bone marrow cell lines, and to a lesser extent, in human endometrial stromal cells, human adult small intestine and human pancreas tumor. PCT application WO 99/14484 reports the fraction of expression in the gastrointestinal system (0.227), reproductive system (0.193), and hematopoietic/immune system (0.168). Finally, this protein is 55% identical and 76% similar to CGI-128 protein, which was isolated from CD34+ cells and is also found in cell lines from the hematopoietic lineage including, HL6 (granulocytic), Jurkat (T-lymphocytic), K562 (erythro-megakaryocytic), and U937 (monocytic).

Supernatant harvested from cells expressing the product of this gene has been shown to increase the permeability of the plasma membrane of renal mesangial cells to calcium. Thus, it is believed that the product of this gene is involved in activating a signal transduction pathway when it binds a receptor on the surface of the plasma membrane of both mesangial cells and other cell types, in addition to other cell-lines or tissue cell types. Thus, polynucleotides and polypeptides have uses, which include, but are not limited to, activating mesangial cells by contacting said cells with a full length polypeptide or a polypeptide fragment which demonstrates this biological activity. Further, the polynucleotides and polypeptides can be used in the methods described in WO9915652, incorporated in its entirety. Binding of a ligand to a receptor is known to alter intracellular levels of small molecules, such as calcium, potassium and sodium, as well as alter pH and membrane potential. Alterations in small molecule concentration can be measured to identify supernatants, which bind to receptors of a particular cell. In addition, when tested against fibroblast cell lines, supernatants removed from cells containing this gene activated the EGR1 (early growth response gene 1) promoter element. Thus, it is likely that this gene activates fibroblast cells through the EGR1 signal transduction pathway. EGR1 is a separate signal transduction pathway from Jak-STAT, genes containing the EGR1 promoter are induced in various tissues and cell types upon activation, leading the cells to undergo differentiation and proliferation (PCT application WO 98/23435)

Polynucleotide comprising sequences encoding the signal peptide of the protein, e.g. VLWLSGLSEPGAA/RQ, can be used in construction of secretion vectors. These vectors would then facilitate the secretion of fusion proteins into the media of cells that have been transfected with the construct of interest. Antibodies which specifically bind the signal peptide could be used to purify the fusion protein from the media if desired.

Polynucleotides and polypeptides of the invention are useful as reagents for differential identification of the tissue(s) or cell type(s) present in a biological sample and for diagnosis of diseases and conditions which include, but are not limited to, haemopoietic and gastrointestinal tract

disorders and stromatosis, in addition to endothelial, mucosal, or epithelial cell disorders. Similarly, polypeptides and antibodies directed to these polypeptides, are useful in providing immunological probes for differential identification of the tissue(s) or cell type(s). For a number of disorders of the above tissues or cells, particularly of the immune and digestive systems, expression of this gene at

5 significantly higher or lower levels may be routinely detected in certain tissues and cell types (e.g. hemaopoietic, immune, reproductive, gastrointestinal, endocrine, and cancerous and wounded tissues) or bodily fluids (e.g. lymph, serum, plasma, urine, synovial fluid and spinal fluid) or another tissue or cell sample taken from an individual having such a disorder, relative to the standard gene expression level, i.e., the expression level in healthy tissue or bodily fluid from an

10 individual not having the disorder.

The tissue distribution in bone marrow cells, fetal liver and fetal kidney, combined with the detected calcium flux and EGR1 biological activity, indicates that polynucleotides and polypeptides corresponding to this gene are useful for immune and gastrointestinal tract disorders, and stromatosis, particularly tumors and proliferative disorders. More specifically, polynucleotides and

15 polypeptides corresponding to this gene are useful for the treatment and diagnosis of hematopoietic related disorders such as anemia, pancytopenia, leukopenia, thrombocytopenia or leukemia since stromal cells are important in the production of cells of hematopoietic lineages. The polypeptides and polynucleotides of the invention can be used to enhance hematopoiesis as described in WO9831385, incorporated in its entirety. The uses include bone marrow cell ex vivo culture, bone

20 marrow transplantation, bone marrow reconstitution, radiotherapy or chemotherapy of neoplasia. The gene product may also be involved in lymphopoiesis, therefore, it can be used in immune disorders such as infection, inflammation, allergy, immunodeficiency etc. In addition, this gene product may have commercial utility in the expansion of stem cells and committed progenitors of various blood lineages, and in the differentiation and/or proliferation of various cell types. Protein

25 as well as, antibodies directed against the protein may show utility as a tumor marker and/or immunotherapy targets for the above listed tissues.

Additionally, since the gene product of 181-16-2-0-A7-CS has been shown to activate the EGR1 promoter element, it likely activates EGR1 signaling activity in fibroblasts. Recent data shows that activation of EGR1 plays a role in wound repair. The cellular transcription factor early

30 growth response factor 1 (Egr1) is expressed minutes after acute injury and serves to stimulate the production of a class of growth factors whose role is to promote tissue repair. Egr-1 expression at the site of dermal wounding in rodents promotes angiogenesis in vitro and in vivo, increases collagen production, and accelerates wound closure. These results show that Egr-1 gene therapy accelerates the normal healing process (Human Gene Ther 2000, vol 11(15):2143-58). Thus, an

35 activator of EGR1 signaling, specifically the gene products of 181-16-2-0-A7-CS (polypeptides and polynucleotides), would be useful in the wound healing process using the methods described in WO9941282 and WO9932135, incorporated by reference in their entireties.

Protein of SEQ ID NO:305 (internal designation 187-37-0-0-c10-CS)

The protein of SEQ ID NO:305, encoded by the cDNA of SEQ ID NO:64, is highly expressed in the prostate and brain. The protein of the invention is strongly homologous to the D9 protein, found in both humans (GNP accession number: U95006 and U95007) and in mice (GNP
5 accession number: U95003, U95004, and U95005). D9 is a myeloid precursor protein transcript regulated by the retinoic acid receptor α , hereafter referred to as RAR- α (Scott et al. Blood 1996; 88: 2517-30).

Retinoic acid is the active metabolite of vitamin A, which contributes to a wide range of biological processes such as cellular differentiation, embryogenesis, and tumor suppression. More
10 specifically, retinoic acid stimulates myeloid precursor differentiation into mature granulocytes. For instance, *in vitro* treatment of acute promyelocytic leukemia blast cells with retinoic acid induces their differentiation (Miyauchi et al. Leuk Lymphoma 1999;33:267-80). In addition, treatment with retinoic acid can induce disease remission in patients affected with promyelocytic leukemia by causing granulocyte precursor differentiation (Slack et al. Ann Hematol 2000;79:227-
15 38).

The diverse range of responses to retinoic acid are mediated by three receptor subtypes: RAR- α , RAR- β , and RAR- γ . RAR- α has been identified as being important for bone marrow maturation of granulocytes (Tsai et al. Genes Dev 1992;6:2258-69). In addition, RAR- α is almost invariably involved in acute promyelocytic leukemia cells by a reciprocal translocation between the
20 long arms of chromosomes 15 and 17 (Alcalay et al., Proc Natl Acad Sci USA 1991;88:1977-81). This type of leukemia is mainly characterized by a predominance of malignant promyelocytes, and severe hemorrhagic manifestations resulting from activation of the coagulation cascade and the fibrinolytic system (Tallman et al. Semin Thromb Hemost 1999;25:209-15). Reciprocal chromosomal translocation leads to the production of a fusion protein that inhibits differentiation
25 and promotes survival of myeloid precursor cells (Grignani et al. Cell 1993;74, 423-431). Transient transfection of a vector containing RAR- α in a promyelocyte cell line causes upregulation in an early manner of several genes, including D9, which is strongly related to protein of SEQ ID NO:305 (Scott et al. Blood 1996; 88: 2517-30). Thus, it is believed that the protein of SEQ ID NO:305 is a myeloid-related protein whose expression is induced by the activation of retinoic acid receptors,
30 including RAR- α .

In a preferred embodiment, the protein of the invention or part thereof may be used to assay the activity of RAR- α protein or retinoic acid in a biological sample. Specifically, as the expression of the protein is believed to be under the direct control of retinoic acid receptors, the level of the protein of the invention, or of the mRNA encoding the protein, can serve as a sensitive and
35 immediate marker for the effects of retinoic acid upon a cell. An ability to detect retinoic acid receptor activation in cells using the present protein has numerous uses. For instance, the protein of the invention or part thereof can be used to monitor the effects of retinoic acid on cells of a patient

undergoing retinoic acid treatment for promyelocytic leukemia (Slack et al. Ann Hematol 2000;79:227-38). As retinoic acid treatment is associated with frequent retarded dose-dependant side effects, it is believed that an assay based on protein of SEQ ID NO:305 could be used to adjust the dose of retinoic acid administered in patients affected with promyelocytic leukemia, in order to
5 predict and avoid such adverse side-effects (Slack et al. Ann Hematol 2000;79:227-38).

In another embodiment, the present polypeptides and polynucleotides can be used to identify myeloid precursors, as well as brain and prostate tissues. The ability to specifically visualize myeloid precursor cells, as well as brain and prostate tissues (and cells derived from the tissues), is useful for any of a number of applications, including to determine the origin or identity
10 of, e.g. cancerous cells, as well as to facilitate the identification of particular cells and tissues for, e.g. the evaluation of histological slides. In addition, such assays can be used to examine the extent of differentiation in myeloid precursor cells.

The present invention further relates to *in vitro* assays and diagnostic kits based on the protein of the present invention or part thereof. Such assays may be used for diagnosis of disorders
15 where the protein activity is abnormally downregulated, such as cancer, and hematological disorders including leukemia. As the protein of SEQ ID NO:305, RAR- α , and acute promyelocytic leukemia are all related, variation in the measured level of the present protein of the invention or part thereof can be used as a diagnostic or screening test for acute promyelocytic leukemia, e.g. using a biological sample such as serum or plasma. Further, an assay that can detect an abnormal
20 level of the protein of the invention or part thereof can be used to detect residual disease in acute promyelocytic leukemia. Such an assay may be used to aid therapeutic decisions in this disorder, e.g. more or less aggressive treatments, the duration of treatment, etc.

In another embodiment, various methods can be used to modulate activity and/or expression of the protein of SEQ ID NO:305, e.g. for the treatment, attenuation and/or prevention of various
25 disorders. In one embodiment, any of a number of reagents, e.g. polynucleotides encoding the protein of SEQ ID NO:305 or a fragment thereof, the protein of SEQ ID NO:305 itself, or a compound that increased the expression or activity of the protein of SEQ ID NO:305, can be administered to a patient suffering from, or at risk of developing, various disorders including cancer, and hematological diseases such as leukemia, and neutropenia. For instance, but not limited
30 to it, proteins or other capable of enhancing the expression or activity of the protein of SEQ ID NO:305 can be administered to treat patients affected with acute promyelocytic leukemia, in order to induce differentiation of the affected cells into mature granulocytes (Slack et al. Ann Hematol 2000;79:227-38). In still another preferred embodiment, proteins or other compounds capable of increasing the expression or activity of the protein of the invention can be used to treat, prevent
35 and/or attenuate neutropenia or agranulocytosis patients, in order to induce *in vivo* differentiation of myeloid precursors into mature granulocytes. In still another preferred embodiment, proteins or other compounds capable of increasing the expression or activity of the protein of SEQ ID NO:305

can be used to treat coagulopathic diseases, such as thrombosis or hemorrhagic manifestations. For instance, they can be used to treat disseminated intravascular coagulation, a severe hemorrhagic syndrome. This embodiment is supported by the fact that acute promyelocytic leukemia is frequently associated with disseminated intravascular coagulation (Tallman et al. Semin Thromb Hemost 1999;25:209-15), and disseminated intravascular coagulation is efficiently corrected with retinoic acid (Dombret et al. Leukemia 1993;7:2-9).

In addition, modulation of the expression or activity of the protein of the invention can be used to modulate differentiation of cells, e.g. promyelocytic leukemia. In one such embodiment, the protein of the invention is inhibited, e.g. using antisense molecules, antibodies, or small molecule inhibitors of the expression or activity of the protein, in order to maintain the undifferentiated state of cells grown in vitro. Alternatively, agents that increase the expression or activity of the protein in cells can be used to induce cellular differentiation, e.g. in the preparation of specific cell types in vitro for particular therapeutic applications.

Protein of SEQ ID NO:248 (internal designation 105-035-2-0-C6-CS) and SEQ ID NO:313 (internal designation 188-28-4-0-D4-CS)

The proteins of SEQ ID NO:248, encoded by the cDNA of SEQ ID NO:7, and SEQ ID NO:313, encoded by the cDNA of SEQ ID NO:72, are highly expressed in brain, liver, pancreas, and testis. The proteins of the invention are nuclear proteins (Miller et al. J Biol Chem 2000;275:32052-6) that display a membrane-spanning segment from amino acids 58 to 78. These proteins are homologous to the human RNA polymerase II elongation factor ELL3 (EMBL accession number AF276512 ; Miller et al. J Biol Chem. 2000; 275:32052-6). In addition, the proteins of SEQ ID NO:248 and SEQ ID NO:313 share sequence homology with two other members of the polymerase II elongation factor family: ELL, and ELL2. The protein of SEQ ID NO:313 is similar to the N-terminal sequence the protein of SEQ ID NO:248, but differs after residue 240 because of a frameshift that produces a premature stop in the sequence SEQ ID NO:72 (Miller et al. J Biol Chem 2000; 275:32052-6). Additionally, the alignment of the protein of SEQ ID NO:248 with occludin, an integral membrane protein found at tight junctions (Furuse et al. J Cell Biol 1994; 127:1617-26), reveals that both proteins display a C-terminal ZO-1 binding domain, with a 26% homology over a 108 amino acid segment. Protein SEQ ID NO:313 lacks this domain, as its C-terminal region is truncated as compared to the protein of SEQ ID NO:248. ZO-1 is part of the family of membrane-associated guanylate kinase homologs (MAGUKs) believed to be important in signal transduction originating from sites of cell-cell contact (Willott et al. Proc Natl Acad Sci USA 1993; 90:7834-8).

The proteins of SEQ ID NOs:248 and 313 are RNA polymerase II elongation factors that increase the catalytic rate of transcription elongation, a phase during which RNA polymerase II moves along the DNA and extends the growing RNA chain (Miller et al. J Biol Chem 2000;

275:32052-6). Specifically, the proteins of SEQ ID NOs:248 and 313 suppress transient pausing at multiple sites along the DNA, thereby altering the K_m and/or the V_{max} of the polymerase (Miller et al. J Biol Chem 2000; 275:32052-6). The present proteins belong to a family that is known to include one virally encoded protein (Tat) and six cellular proteins (SIX, P-TEFb, TFIIF, Elongin
5 (SII), ELL and ELL2).

A growing body of evidence suggests that mis-regulation of elongation may be a key element in a variety of human diseases (see, Aso et al. J Clin Invest 1996; 97:1561-9). For instance, two RNA polymerase II elongation proteins have been implicated in oncogenesis: ELL, which is a frequent target for translocation in acute myeloid leukemia (Thirman et al. Proc Natl Acad Sci USA
10 1994; 91:12110-4 ; Mitani et al. Blood 1995;85:2017-24), and elongin, which is a transcription factor regulated by the product of the von Hippel-Lindau tumor suppressor gene, which is itself mutated in the majority of clear-cell renal carcinomas and in families with von Hippel-Lindau disease (Duan et al. Science 1995;269:1402-6, Kibel et al. Science 1995; 269:1444-6). In addition, overexpression of ELL leads to the transformation of fibroblasts (Kanda et al. J Biol Chem. 1998
15 27; 273:5248-52). Thus, the proteins of SEQ ID NOs:248 and 313 may be important for oncogenesis of multiple types of neoplastic diseases, especially hematological malignancies.

In one embodiment, the present proteins are used to increase the rate of transcription in vitro. Such an increase can be used for any of the large number of in vitro transcription reactions which are routinely used for molecular biological applications, e.g. for the preparation of RNA, for
20 protein production, for the characterization of promoters and transcription factors, etc.

In another embodiment, the present invention provides diagnostic tools for the detection of mutations in the genes encoding SEQ ID NOs:248 or 313. Such mutations may be detected by a variety of techniques, including RNase and S1 protection assays; alterations in electrophoretic mobility of DNA fragments in gels, with or without denaturing agents such as SSCP or DGGE;
25 dHPLC; and direct DNA sequencing. The detection of mutations in the genes encoding SEQ ID NOs:248 or 313 are useful for the detection of a number of diseases and conditions, such as cancers and hematological malignancies including leukemia. For example, the RNA polymerase II Elongation Factor ELL gene undergoes frequent translocations in acute myeloid leukemia (Thirman et al. Proc Natl Acad Sci USA 1994; 91:12110-4 ; Mitani et al. Blood 1995; 85:2017-24), and it is
30 likely that other elongation factors are involved in additional such diseases.

Another embodiment of the present inventions relates to compositions and methods for using the proteins or part thereof to specifically visualize myeloid precursor cells, as well as pancreas, liver and testis tissues (and cells derived from the tissues). The ability to detect such cell types is useful for any of a number of applications, including to determine the origin or identity of,
35 e.g. cancerous cells, as well as to facilitate the identification of particular cells and tissues for, e.g. the evaluation of histological slides. In addition, such methods can be used to examine the extent of differentiation in myeloid or myeloid-progenitor cells for staging of leukemia or any other

neoplastic disorder. Any method for detecting the presence of the proteins of the invention, or nucleic acids encoding the proteins, can be used, including methods involving the use of antibodies immunospecific for the proteins of invention. Such antibodies can be used in various methods including radioimmunoassays, competitive binding assays, Western Blot analysis and enzyme-linked immunosorbant assay (ELISA) assays, or any other technique known to those skilled in the art. In another embodiment, the present protein or part thereof can be used for the treatment, attenuation and/or prevention of conditions associated with unbalanced amounts and/or activity of the protein of SEQ ID NO:248 or 313. Other modulatory substances can also be used in such embodiments, including chemical compounds such as agonists and antagonists, nucleic acids including antisense and ribozyme sequences, and antibodies. In a preferred embodiment, such substances are employed for the treatment or prevention of certain types of neoplastic disorders associated such as cancer or hematological malignancies such as leukemia. In such embodiments, where an increased level of expression or activity of the present proteins is correlated with the presence of a disease such as cancer, the disease can be treated or prevented using any agent that can provoke a decrease in the level of activity or expression of the protein, such as antibodies, antisense molecules, ribozymes, dominant negative forms of the protein, compounds that inhibit the expression or activity of the proteins, and others. Alternatively, in cases where a decreased level of expression or activity of the proteins is correlated with the presence of a disease such as cancer, the disease can be treated using any agent that can cause an increase in the expression or activity of the protein, such as polynucleotides encoding the proteins, purified forms of the proteins, or any compound that causes an increase in the expression or activity of the proteins. Further, any detection of a correlation between the level of expression or activity of the protein and the presence or absence of a disease can be used to develop diagnostic or screening tools for the detection of the disease itself, or of a predisposition for the disease.

25 Uses of antibodies

Antibodies of the present invention have uses that include, but are not limited to, methods known in the art to purify, detect, and target the polypeptides of the present invention including both *in vitro* and *in vivo* diagnostic and therapeutic methods. An example of such use using immunoaffinity chromatography is given below. The antibodies of the present invention may be used either alone or in combination with other compositions. For example, the antibodies have use in immunoassays for qualitatively and quantitatively measuring levels of antigen-bearing substances, including the polypeptides of the present invention, in biological samples (*See, e.g., Harlow et al., 1988*). (Incorporated by reference in the entirety). The antibodies may also be used in therapeutic compositions for killing cells expressing the protein or reducing the levels of the protein in the body.

The invention further relates to antibodies that act as agonists or antagonists of the polypeptides of the present invention. For example, the present invention includes antibodies that

disrupt the receptor/ligand interactions with the polypeptides of the invention either partially or fully. Included are both receptor-specific antibodies and ligand-specific antibodies. Included are receptor-specific antibodies, which do not prevent ligand binding but prevent receptor activation. Receptor activation (i.e., signaling) may be determined by techniques described herein or otherwise
5 known in the art. Also include are receptor-specific antibodies which both prevent ligand binding and receptor activation. Likewise, included are neutralizing antibodies that bind the ligand and prevent binding of the ligand to the receptor, as well as antibodies that bind the ligand, thereby preventing receptor activation, but do not prevent the ligand from binding the receptor. Further included are antibodies that activate the receptor. These antibodies may act as agonists for either all
10 or less than all of the biological activities affected by ligand-mediated receptor activation. The antibodies may be specified as agonists or antagonists for biological activities comprising specific activities disclosed herein. The above antibody agonists can be made using methods known in the art. *See e.g.*, WO 96/40281; US Patent 5,811,097; Deng *et al.* (1998); Chen *et al.* (1998); Harrop *et al.* (1998); Zhu *et al.* (1998); Yoon *et al.* (1998); Prat *et al.* (1998); Pitard *et al.* (1997); Liautard *et al.* (1997); Carlson *et al.* (1997); Taryman *et al.* (1995); Muller *et al.* (1998); Bartunek *et al.* (1996)
15 (said references incorporated by reference in their entireties).

As discussed above, antibodies of the polypeptides of the invention can, in turn, be utilized to generate anti-idiotypic antibodies that “mimic” polypeptides of the invention using techniques well known to those skilled in the art (*See, e.g.* Greenspan and Bona (1989) and Nissinoff (1991),
20 which disclosures are hereby incorporated by reference in their entireties). For example, antibodies which bind to and competitively inhibit polypeptide multimerization or binding of a polypeptide of the invention to ligand can be used to generate anti-idiotypes that “mimic” the polypeptide multimerization or binding domain and, as a consequence, bind to and neutralize polypeptide or its ligand. Such neutralization anti-idiotypic antibodies can be used to bind a polypeptide of the
25 invention or to bind its ligands/receptors, and thereby block its biological activity.

Immunoaffinity Chromatography

Antibodies prepared as described herein are coupled to a support. Preferably, the antibodies are monoclonal antibodies, but polyclonal antibodies may also be used. The support may be any of those typically employed in immunoaffinity chromatography, including Sepharose CL-4B
30 (Pharmacia, Piscataway, NJ), Sepharose CL-2B (Pharmacia, Piscataway, NJ), Affi-gel 10 (Biorad, Richmond, CA), or glass beads.

The antibodies may be coupled to the support using any of the coupling reagents typically used in immunoaffinity chromatography, including cyanogen bromide. After coupling the antibody to the support, the support is contacted with a sample which contains a target polypeptide whose
35 isolation, purification or enrichment is desired. The target polypeptide may be a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides

included in SEQ ID Nos: 242-272 and 274-384 as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool, variants and fragments thereof, or a fusion protein comprising said selected polypeptide or a fragment thereof.

Preferably, the sample is placed in contact with the support for a sufficient amount of time
5 and under appropriate conditions to allow at least 50% of the target polypeptide to specifically bind to the antibody coupled to the support.

Thereafter, the support is washed with an appropriate wash solution to remove polypeptides which have non-specifically adhered to the support. The wash solution may be any of those typically employed in immunoaffinity chromatography, including PBS, Tris-lithium chloride buffer
10 (0.1M lysine base and 0.5M lithium chloride, pH 8.0), Tris-hydrochloride buffer (0.05M Tris-hydrochloride, pH 8.0), or Tris/Triton/NaCl buffer (50mM Tris.cl, pH 8.0 or 9.0, 0.1% Triton X-100, and 0.5MNaCl).

After washing, the specifically bound target polypeptide is eluted from the support using the high pH or low pH elution solutions typically employed in immunoaffinity chromatography. In
15 particular, the elution solutions may contain an eluant such as triethanolamine, diethylamine, calcium chloride, sodium thiocyanate, potassium bromide, acetic acid, or glycine. In some embodiments, the elution solution may also contain a detergent such as Triton X-100 or octyl-beta-D-glucoside.

Import vectors

20 The GENSET polypeptides of the invention may also be used as a carrier to import a protein or peptide of interest, so-called cargo, into tissue-culture cells or in host organisms. A hydrophobic region of a GENSET polypeptide or a fragment thereof, preferably the signal peptide of a sequence selected from the group consisting of of SEQ ID Nos: 1-31 and 33-143 and clones
inserts of the deposited clone pool, more preferably the short core hydrophobic region (h) of signal
25 peptides may be used as a carrier.

When cell permeable peptides of limited size (approximately up to 25 amino acids) are to be translocated across cell membrane, chemical synthesis may be used in order to add the h region to either the C-terminus or the N-terminus to the cargo peptide of interest. Alternatively, when
longer peptides or proteins are to be imported into cells, nucleic acids can be genetically engineered,
30 using techniques familiar to those skilled in the art, in order to link the cDNA sequence or fragment thereof encoding the hydrophobic region to the 5' or the 3' end of a DNA sequence coding for a cargo polypeptide. Such genetically engineered nucleic acids are then translated either *in vitro* or *in vivo* after transfection into appropriate cells, using conventional techniques to produce the resulting cell permeable polypeptide. Suitable hosts cells are then simply incubated with the cell permeable
35 polypeptide which is then translocated across the membrane.

This method may be applied to study diverse intracellular functions and cellular processes. For instance, it has been used to probe functionally relevant domains of intracellular proteins and to examine protein-protein interactions involved in signal transduction pathways (Lin *et al.*, *J. Biol. Chem.*, 270: 14225-14258 (1995); Lin *et al.*, *J. Biol. Chem.*, 271: 5305-5308 (1996); Rojas *et al.*, *J. Biol. Chem.*, 271: 27456-27461 (1996); Rojas *et al.*, *Nature Biotech.*, 16: 370-375 (1998); Liu *et al.*, *Proc. Natl. Acad. Sci. USA*, 93: 11819-11824 (1996); Rojas *et al.*, *Bioch. Biophys. Res. Commun.*, 234: 675-680 (1997) Du *et al.*, *J. Peptide Res.*, 51: 235-243 (1998)).

Such techniques may be used in cellular therapy to import proteins producing therapeutic effects. For instance, cells isolated from a patient may be treated with imported therapeutic proteins and then re-introduced into the host organism.

Alternatively, the hydrophobic region of signal peptides of the present invention could be used in combination with a nuclear localization signal to deliver nucleic acids into cell nucleus. Such oligonucleotides may be antisense oligonucleotides or oligonucleotides designed to form triple helixes, as described herein, in order to respectively inhibit processing or maturation of a target cellular RNA.

EXPRESSION OF GENSET PRODUCTS

Spatial expression of the GENSET genes of the invention

Tissue expression of the cDNAs of the present invention was examined. Table IX list the Genset's libraries of tissues and cell types examined that express the polynucleotides of the present invention. The tissues and cell types examined for polynucleotide expression were: adrenal gland (AG), bone marrow (BM), brain (Br), cancerous prostate (CP), cerebellum (Ce), colon (Co), dystrophic muscle (DM), fetal brain (FB), fetal kidney (FK), fetal liver (FL), heart (He), hypertrophic prostate (HP), kidney (Ki), liver (Li), lung (Lu), lung cells (LC), lymph ganglia (LG), lymphocytes (Ly), muscle (Mu), Ovary (Ov), pancreas (Pa), pituitary gland (PG), placenta (Pl), prostate (Pr), salivary gland (SG), spinal cord (SC), spleen (Sp), stomach/intestine (SI), substantia nigra (SN), testis (Te), thyroid (Ty), umbilical cord (UC) and uterus (Ut).

For each cDNA referred to by its sequence identification number (first column), the number of proprietary 5'ESTs (i.e. cDNA fragments) expressed in a particular tissue referred to by its name is indicated after a semi column (second column). In addition, the bias in the spatial distribution of the polynucleotide sequences of the present invention was examined by comparing the relative proportions of the biological polynucleotides of a given tissue using the following statistical analysis. The under- or over-representation of a polynucleotide of a given cluster in a given tissue was performed using the normal approximation of the binomial distribution. When the observed proportion of a polynucleotide of a given tissue in a given consensus had less than 1% chance to occur randomly according to the chi2 test, the frequency bias was reported as "preferred". The results are given in Table X as follows. For each polynucleotide showing a bias in tissue distribution

as referred to by its sequence identification number in the first column, the list of tissues where the polynucleotides are under-represented is given in the second column entitled "low frequency expression" and the list of tissues where the polynucleotides are over-represented is given in the third column entitled "high frequency expression".

5 The cellular localization of some polypeptides of the invention was also determined using the "psort software" (Nakai, and Horton, (1999); Nakai and Kanehisa, (1992), which disclosures are hereby incorporated by reference in their entireties). For each polypeptide identified by its sequence identification number in the first column, the second column of Table XI list the predicted subcellular localization.

10 Evaluation of Expression Levels and Patterns of GENSET mRNAs

The spatial and temporal expression patterns of GENSET mRNAs, as well as their expression levels, may also be further determined as follows.

Expression levels and patterns of GENSET mRNAs may be analyzed by solution hybridization with long probes as described in International Patent Application No. WO 97/05277, the entire contents of which are hereby incorporated by reference. Briefly, a GENSET
15 polynucleotide, or fragment thereof corresponding to the gene encoding the mRNA to be characterized is inserted at a cloning site immediately downstream of a bacteriophage (T3, T7 or SP6) RNA polymerase promoter to produce antisense RNA. Preferably, the GENSET polynucleotide is at least a 100 nucleotides in length. The plasmid is linearized and transcribed in
20 the presence of ribonucleotides comprising modified ribonucleotides (i.e. biotin-UTP and DIG-UTP). An excess of this doubly labeled RNA is hybridized in solution with mRNA isolated from cells or tissues of interest. The hybridizations are performed under standard stringent conditions (40-50°C for 16 hours in an 80% formamide, 0.4 M NaCl buffer, pH 7-8). The unhybridized probe is removed by digestion with ribonucleases specific for single-stranded RNA (i.e. RNases CL3, T1,
25 Phy M, U2 or A). The presence of the biotin-UTP modification enables capture of the hybrid on a microtitration plate coated with streptavidin. The presence of the DIG modification enables the hybrid to be detected and quantified by ELISA using an anti-DIG antibody coupled to alkaline phosphatase.

The GENSET cDNAs, or fragments thereof may also be tagged with nucleotide sequences
30 for the serial analysis of gene expression (SAGE) as disclosed in UK Patent Application No. 2 305 241 A, the entire contents of which are incorporated by reference. In this method, cDNAs are prepared from a cell, tissue, organism or other source of nucleic acid for which it is desired to determine gene expression patterns. The resulting cDNAs are separated into two pools. The cDNAs in each pool are cleaved with a first restriction endonuclease, called an "anchoring enzyme,"
35 having a recognition site which is likely to be present at least once in most cDNAs. The fragments which contain the 5' or 3' most region of the cleaved cDNA are isolated by binding to a capture

medium such as streptavidin coated beads. A first oligonucleotide linker having a first sequence for hybridization of an amplification primer and an internal restriction site for a "tagging endonuclease" is ligated to the digested cDNAs in the first pool. Digestion with the second endonuclease produces short "tag" fragments from the cDNAs. A second oligonucleotide having a second sequence for hybridization of an amplification primer and an internal restriction site is ligated to the digested cDNAs in the second pool. The cDNA fragments in the second pool are also digested with the "tagging endonuclease" to generate short "tag" fragments derived from the cDNAs in the second pool. The "tags" resulting from digestion of the first and second pools with the anchoring enzyme and the tagging endonuclease are ligated to one another to produce "ditags." In some embodiments, the ditags are concatamerized to produce ligation products containing from 2 to 200 ditags. The tag sequences are then determined and compared to the sequences of the GENSET cDNAs to determine which genes are expressed in the cell, tissue, organism, or other source of nucleic acids from which the tags were derived. In this way, the expression pattern of a GENSET gene in the cell, tissue, organism, or other source of nucleic acids is obtained.

Quantitative analysis of GENSET gene expression may also be performed using arrays. For example, quantitative analysis of gene expression may be performed with GENSET polynucleotides, or fragments thereof in a complementary DNA microarray as described by Schena *et al.* (1995 and 1996) which disclosures are hereby incorporated by reference in their entireties. GENSET cDNAs or fragments thereof are amplified by PCR and arrayed from 96-well microtiter plates onto silylated microscope slides using high-speed robotics. Printed arrays are incubated in a humid chamber to allow rehydration of the array elements and rinsed, once in 0.2% SDS for 1 min, twice in water for 1 min and once for 5 min in sodium borohydride solution. The arrays are submerged in water for 2 min at 95°C, transferred into 0.2% SDS for 1 min, rinsed twice with water, air dried and stored in the dark at 25°C. Cell or tissue mRNA is isolated or commercially obtained and probes are prepared by a single round of reverse transcription. Probes are hybridized to 1 cm² microarrays under a 14 x 14 mm glass coverslip for 6-12 hours at 60°C. Arrays are washed for 5 min at 25°C in low stringency wash buffer (1X SSC/0.2% SDS), then for 10 min at room temperature in high stringency wash buffer (0.1X SSC/0.2% SDS). Arrays are scanned in 0.1X SSC using a fluorescence laser scanning device fitted with a custom filter set. Accurate differential expression measurements are obtained by taking the average of the ratios of two independent hybridizations.

Quantitative analysis of the expression of genes may also be performed with GENSET cDNAs or fragments thereof in complementary DNA arrays as described by Pietu *et al.* (1996), which disclosure is hereby incorporated by reference in its entirety. The GENSET polynucleotides of the invention or fragments thereof are PCR amplified and spotted on membranes. Then, mRNAs originating from various tissues or cells are labeled with radioactive nucleotides. After hybridization and washing in controlled conditions, the hybridized mRNAs are detected by

phospho-imaging or autoradiography. Duplicate experiments are performed and a quantitative analysis of differentially expressed mRNAs is then performed.

Alternatively, expression analysis of GENSET genes can be done through high density nucleotide arrays as described by Lockhart *et al.* (1996) and Sosnowski *et al.* (1997), which disclosures are hereby incorporated by reference in their entireties. Oligonucleotides of 15-50 nucleotides corresponding to sequences of a GENSET polynucleotide or fragments thereof are synthesized directly on the chip (Lockhart *et al.*, supra) or synthesized and then addressed to the chip (Sosnowski *et al.*, supra). Preferably, the oligonucleotides are about 20 nucleotides in length. cDNA probes labeled with an appropriate compound, such as biotin, digoxigenin or fluorescent dye, are synthesized from the appropriate mRNA population and then randomly fragmented to an average size of 50 to 100 nucleotides. The said probes are then hybridized to the chip. After washing as described in Lockhart *et al.*, (supra) and application of different electric fields (Sosnowski *et al.*, supra), the dyes or labeling compounds are detected and quantified. Duplicate hybridizations are performed. Comparative analysis of the intensity of the signal originating from cDNA probes on the same target oligonucleotide in different cDNA samples indicates a differential expression of the GENSET mRNA.

Uses of GENSET expression data

Once the expression levels and patterns of a GENSET mRNA has been determined using any technique known to those skilled in the art, in particular those described in the section entitled “Evaluation of Expression Levels and Patterns of GENSET mRNAs”, or using the instant disclosure, these information may be used to design GENSET specific markers for detection, identification, screening and diagnosis purposes as well as to design DNA constructs with an expression pattern similar to a GENSET expression pattern.

Detection of GENSET expression and/or biological activity

The invention further relates to methods of detection of GENSET expression and/or biological activity in a biological sample using the polynucleotide and polypeptide sequences described herein. Such method scan be used, for example, as a screen for normal or abnormal GENSET expression and/or biological activity and, thus, can be used diagnostically. The biological sample for use in the methods of the present invention includes a suitable sample from, for example, a mammal, particularly a human. For example, the sample can be issued from tissues or cell lines having the same origin as tissues or cell lines in which the polypeptide is known to be expressed using the data from Table IX.

Detection of GENSET products

The invention further relates to methods of detection of GENSET polynucleotides or polypeptides in a sample using the sequences described herein and any techniques known to those

skilled in the art. For example, a labeled polynucleotide probe having all or a functional portion of the nucleotide sequence of a GENSET polynucleotide can be used in a method to detect a GENSET polynucleotide in a sample. In one embodiment, the sample is treated to render the polynucleotides in the sample available for hybridization to a polynucleotide probe, which can be DNA or RNA.

- 5 The resulting treated sample is combined with a labeled polynucleotide probe having all or a portion of the nucleotide sequence of the GENSET cDNA or genomic sequence, under conditions appropriate for hybridization of complementary sequences to occur. Detection of hybridization of polynucleotides from the sample with the labeled nucleic probe indicates the presence of GENSET polynucleotides in a sample. The presence of GENSET mRNA is indicative of GENSET
10 expression.

Consequently, the invention comprises methods for detecting the presence of a polynucleotide comprising a nucleotide sequence selected from a group consisting of the sequences of SEQ ID Nos: 1-241, the sequences of clone inserts of the deposited clone pool, sequences fully complementary thereto, fragments and variants thereof in a sample. In a first embodiment, said
15 method comprises the following steps of:

- a) bringing into contact said sample and a nucleic acid probe or a plurality of nucleic acid probes which hybridize to said selected nucleotide sequence; and
- b) detecting the hybrid complex formed between said probe or said plurality of probes and said polynucleotide.

20 In a preferred embodiment of the above detection method, said nucleic acid probe or said plurality of nucleic acid probes is labeled with a detectable molecule. In another preferred embodiment of the above detection method, said nucleic acid probe or said plurality of nucleic acid probes has been immobilized on a substrate. In still another preferred embodiment, said nucleic acid probe or said plurality of nucleic acid probes has a sequence comprised in a sequence
25 complementary to said selected sequence.

In a second embodiment, said method comprises the following steps of:

- a) contacting said sample with amplification reaction reagents comprising a pair of amplification primers located on either side of the region of said nucleotide sequence to be amplified;
- 30 b) performing an amplification reaction to synthesize amplification products containing said region of said selected nucleotide sequence; and
- c) detecting said amplification products.

In a preferred embodiment of the above detection method, when the polynucleotide to be amplified is a RNA molecule, preliminary reverse transcription and synthesis of a second cDNA
35 strand are necessary to provide a DNA template to be amplified. In another preferred embodiment of the above detection method, the amplification product is detected by hybridization with a labeled probe having a sequence which is complementary to the amplified region. In still another preferred

embodiment, at least one of said amplification primer has a sequence comprised in said selected sequence or in the sequence complementary to said selected sequence.

Alternatively, a method of detecting GENSET expression in a test sample can be accomplished using any product which binds to a GENSET polypeptide of the present invention or
5 a portion of a GENSET polypeptide. Such products may be antibodies, binding fragments of antibodies, polypeptides able to bind specifically to GENSET polypeptides or fragments thereof, including GENSET agonists and antagonists. Detection of specific binding to the antibody indicates the presence of a GENSET polypeptide in the sample (e.g., ELISA).

Consequently, the invention is also directed to a method for detecting specifically the
10 presence of a GENSET polypeptide according to the invention in a biological sample, said method comprising the following steps of:

- a) bringing into contact said biological sample with a product able to bind to a polypeptide of the invention or fragments thereof;
- b) allowing said product to bind to said polypeptide to form a complex; and
15 b) detecting said complex.

In a preferred embodiment of the above detection method, the product is an antibody. In a more preferred embodiment, said antibody is labeled with a detectable molecule. In another more preferred embodiment of the above detection method, said antibody has been immobilized on a substrate.

20 In addition, the invention also relates to methods of determining whether a GENSET product (e.g. a polynucleotide or polypeptide) is present or absent in a biological sample, said methods comprising the steps of:

- a) obtaining said biological sample from a human or non-human animal, preferably a mammal;
- 25 b) contacting said biological sample with a product able to bind to a GENSET polynucleotide or polypeptide of the invention; and
- c) determining the presence or absence of said GENSET product in said biological sample.

Compounds that specifically binds a GENSET product may either be compounds binding to a GENSET polypeptide (e.g. binding proteins, antibodies or binding fragments thereof (e.g. F(ab')₂
30 fragments) or compounds binding to a GENSET polynucleotide (e.g. a complementary probe or primer).

The present invention also relates to kits that can be used in the detection of GENSET expression products. The kit can comprise a compound that specifically binds a GENSET polypeptide (e.g. binding proteins, antibodies or binding fragments thereof (e.g. F(ab')₂ fragments)
35 or a GENSET mRNA (e.g. a complementary probe or primer), for example, disposed within a container means. The kit can further comprise ancillary reagents, including buffers and the like.

Detection of a GENSET biological activity

The invention further includes methods of detecting specifically a GENSET biological activity. Assessing the GENSET biological activity may be performed using a variety of techniques, including those described in the section entitled “**Erreur! Source du renvoi introuvable.**”.

5 Consequently, the invention is directed to a method for detecting specifically GENSET biological activity in a biological sample, said method comprising the following steps:

- a) obtaining a biological sample from a human or non-human mammal; and
- b) detecting a GENSET biological activity.

 The present invention also relates to kits that can be used in the detection of GENSET
10 biological activity.

Identification of a specific context of GENSET expression

 When the expression pattern of a GENSET mRNA shows that a GENSET gene is specifically expressed in a given context, probes and primers specific for this gene as well as antibodies binding to the GENSET polynucleotide may then be used as markers for a specific
15 context. Examples of specific contexts are: specific expression in a given tissue/cell or tissue/cell type, expression at a given stage of development of a process such as embryo development or disease development, or specific expression in a given organelle. Such primers, probes, and antibodies are useful commercially to identify tissues/cells/organelles of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites,
20 or to differentiate different tissue types in a tissue cross-section using any technique known to those skilled in the art including *in situ* PCR or immunochemistry for example.

 For example, the cDNAs and proteins of the sequence listing and fragments thereof, may be used to distinguish human tissues/cells from non-human tissues/cells and to distinguish between human tissues/cells/organelles that do and do not express the polynucleotides comprising the
25 cDNAs. By knowing the expression pattern of a given GENSET, either through routine experimentation or by using the instant disclosure, the polynucleotides and polypeptides of the present invention may be used in methods of determining the identity of an unknown tissue/cell sample/organelle. As part of determining the identity of an unknown tissue/cell sample/organelle, the polynucleotides and polypeptides of the present invention may be used to determine what the
30 unknown tissue/cell sample is and what the unknown sample is not. For example, if a cDNA is expressed in a particular tissue/cell type/organelle, and the unknown tissue/cell sample/organelle does not express the cDNA, it may be inferred that the unknown tissue/cells are either not human or not the same human tissue/cell type/organelle as that which expresses the cDNA. These methods of determining tissue/cell/organelle identity are based on methods which detect the presence or
35 absence of the mRNA (or corresponding cDNA) in a tissue/cell sample using methods well known in the art (e.g., hybridization, PCR based methods, immunoassays, immunochemistry, ELISA).

Examples of such techniques are described in more detail below. Therefore, the invention encompasses uses of the polynucleotides and polypeptides of the invention as tissue markers. In a preferred embodiment, polynucleotides preferentially expressed in given tissues as indicated in Table X and polypeptides encoded by such polynucleotides are used for this purpose. The invention also encompasses uses of polypeptides of the invention as organelle markers. In a preferred embodiment, polypeptides preferentially expressed in given subcellular compartment as indicated in Table XI are used for this purpose.

Consequently, the present invention encompasses methods of identification of a tissue/cell type/subcellular compartment, wherein said method includes the steps of:

- a) contacting a biological sample which identity is to be assayed with a product able to bind a GENSET product; and

- b) determining whether a GENSET product is expressed in said biological sample.

Products that are able to bind specifically to a GENSET product, namely a GENSET polypeptide or a GENSET mRNA, include GENSET binding proteins, antibodies or binding fragments thereof (e.g. F(ab')₂ fragments), as well as GENSET complementary probes and primers.

Step b) may be performed using any detection method known to those skilled in the art including those disclosed herein, especially in the section entitled "Detection of GENSET expression and/or biological activity"..

20 *Identification of Tissue Types or Cell Species by Means of Labeled Tissue Specific Antibodies*

Identification of specific tissues is accomplished by the visualization of tissue specific antigens by means of antibody preparations which are conjugated, directly (e.g., green fluorescent protein) or indirectly to a detectable marker. Selected labeled antibody species bind to their specific antigen binding partner in tissue sections, cell suspensions, or in extracts of soluble proteins from a tissue sample to provide a pattern for qualitative or semi-qualitative interpretation.

Antisera for these procedures must have a potency exceeding that of the native preparation, and for that reason, antibodies are concentrated to a mg/ml level by isolation of the gamma globulin fraction, for example, by ion-exchange chromatography or by ammonium sulfate fractionation. Also, to provide the most specific antisera, unwanted antibodies, for example to common proteins, must be removed from the gamma globulin fraction, for example by means of insoluble immunoabsorbents, before the antibodies are labeled with the marker. Either monoclonal or heterologous antisera is suitable for either procedure.

A. Immunohistochemical Techniques

Purified, high-titer antibodies, prepared as described above, are conjugated to a detectable marker, as described, for example, by Fudenberg, (1980) or Rose *et al.*, (1980), which disclosures are hereby incorporated by reference in their entirety.

A fluorescent marker, either fluorescein or rhodamine, is preferred, but antibodies can also be labeled with an enzyme that supports a color producing reaction with a substrate, such as horseradish peroxidase. Markers can be added to tissue-bound antibody in a second step, as described below. Alternatively, the specific anti-tissue antibodies can be labeled with ferritin or
5 other electron dense particles, and localization of the ferritin coupled antigen-antibody complexes achieved by means of an electron microscope. In yet another approach, the antibodies are radiolabeled, with, for example ^{125}I , and detected by overlaying the antibody treated preparation with photographic emulsion. Preparations to carry out the procedures can comprise monoclonal or polyclonal antibodies to a single protein or peptide identified as specific to a tissue type, for
10 example, brain tissue, or antibody preparations to several antigenically distinct tissue specific antigens can be used in panels, independently or in mixtures, as required. Tissue sections and cell suspensions are prepared for immunohistochemical examination according to common histological techniques. Multiple cryostat sections (about 4 μm , unfixed) of the unknown tissue and known control, are mounted and each slide covered with different dilutions of the antibody preparation.
15 Sections of known and unknown tissues should also be treated with preparations to provide a positive control, a negative control, for example, pre-immune sera, and a control for non-specific staining, for example, buffer. Treated sections are incubated in a humid chamber for 30 min at room temperature, rinsed, then washed in buffer for 30-45 min. Excess fluid is blotted away, and the marker developed. If the tissue specific antibody was not labeled in the first incubation, it can
20 be labeled at this time in a second antibody-antibody reaction, for example, by adding fluorescein- or enzyme-conjugated antibody against the immunoglobulin class of the antiserum-producing species, for example, fluorescein labeled antibody to mouse IgG. Such labeled sera are commercially available. The antigen found in the tissues by the above procedure can be quantified by measuring the intensity of color or fluorescence on the tissue section, and calibrating that signal
25 using appropriate standards.

B. Identification of Tissue Specific Soluble Proteins

The visualization of tissue specific proteins and identification of unknown tissues from that procedure is carried out using the labeled antibody reagents and detection strategy as described for immunohistochemistry; however the sample is prepared according to an electrophoretic technique
30 to distribute the proteins extracted from the tissue in an orderly array on the basis of molecular weight for detection. A tissue sample is homogenized using a Virtis apparatus; cell suspensions are disrupted by Dounce homogenization or osmotic lysis, using detergents in either case as required to disrupt cell membranes, as is the practice in the art. Insoluble cell components such as nuclei, microsomes, and membrane fragments are removed by ultracentrifugation, and the soluble protein-
35 containing fraction concentrated if necessary and reserved for analysis. A sample of the soluble protein solution is resolved into individual protein species by conventional SDS polyacrylamide

electrophoresis as described, for example, by Davis *et al.*, Section 19-2 (1986), using a range of amounts of polyacrylamide in a set of gels to resolve the entire molecular weight range of proteins to be detected in the sample. A size marker is run in parallel for purposes of estimating molecular weights of the constituent proteins. Sample size for analysis is a convenient volume of from 5 to 55
5 ul, and containing from about 1 to 100 ug protein. An aliquot of each of the resolved proteins is transferred by blotting to a nitrocellulose filter paper, a process that maintains the pattern of resolution. Multiple copies are prepared. The procedure, known as Western Blot Analysis, is well described in Davis *et al.*, (1986) Section 19-3. One set of nitrocellulose blots is stained with Coomassie Blue dye to visualize the entire set of proteins for comparison with the antibody bound
10 proteins. The remaining nitrocellulose filters are then incubated with a solution of one or more specific antisera to tissue specific proteins prepared as described herein. In this procedure, as in procedure A above, appropriate positive and negative sample and reagent controls are run.

In either procedure A or B, a detectable label can be attached to the primary tissue antigen-
primary antibody complex according to various strategies and permutations thereof. In a
15 straightforward approach, the primary specific antibody can be labeled; alternatively, the unlabeled complex can be bound by a labeled secondary anti-IgG antibody. In other approaches, either the primary or secondary antibody is conjugated to a biotin molecule, which can, in a subsequent step, bind an avidin conjugated marker. According to yet another strategy, enzyme labeled or radioactive protein A, which has the property of binding to any IgG, is bound in a final step to either the
20 primary or secondary antibody. The visualization of tissue specific antigen binding at levels above those seen in control tissues to one or more tissue specific antibodies, prepared from the gene sequences identified from cDNA sequences, can identify tissues of unknown origin, for example, forensic samples, or differentiated tumor tissue that has metastasized to foreign bodily sites.

Targeting of compounds to subcellular compartments

25 GENSET Polypeptides expressed in specific cellular compartments/organelles may also be used to target compounds to these compartments/organelles. The invention therefore encompasses uses of polypeptides and polynucleotides of the invention as organelle targeting tools.

In a first embodiment, GENSET polypeptides expressed in mitochondria may be used to target heterologous compounds, either polypeptides or polynucleotides to mitochondria by
30 recombinantly or chemically fusing a fragment of the protein of the invention to an heterologous polypeptide or polynucleotide. Preferred fragments are signal peptide, amphiphilic alpha helices and/or any other fragments of the protein of the invention, or part thereof, that may contain targeting signals for mitochondria including but not limited to matrix targeting signals as defined in Herrman and Neupert, (2000); Bhagwat *et al.* (1999), Murphy (1997); Glaser *et al.* (1998);
35 Ciminale *et al.* (1999), which disclosures are hereby incorporated by reference in their entireties. Such heterologous compounds may be used to modulate mitochondria's activities. For example,

they may be used to induce and/or prevent mitochondrial-induced apoptosis or necrosis. In addition, heterologous polynucleotides may be used for mitochondrial gene therapy to replace a defective mitochondrial gene and/or to inhibit the deleterious expression of a mitochondrial gene.

In a second embodiment, GENSET polypeptides expressed in the endoplasmic reticulum may be used to target heterologous polypeptides to the endoplasmic reticulum by recombinantly or chemically fusing a fragment of the proteins of the invention to an heterologous polypeptide. Preferred fragments are any fragments of the proteins of the invention, or part thereof, that may contain targeting signals for the endoplasmic reticulum such as those described in Pidoux and Armstrong (1992), Munro and Pelham (1987); Pelham (1990), which disclosures are hereby incorporated by reference in their entireties.

In a third embodiment, GENSET polypeptides expressed in the nucleus may be used to target heterologous polypeptides or polynucleotides to the nucleus by recombinantly or chemically fusing a fragment of the proteins or polynucleotide of the invention to an heterologous polypeptide or polynucleotide. Preferred fragments are any fragments of the proteins or polynucleotide of the invention, or part thereof, that may contain targeting signals for the nucleus (nuclear localization signals) such as those described in Christophe et al. (2000), which disclosure is hereby incorporated by reference in its entirety.

In a fourth embodiment, GENSET polypeptides expressed in the nucleus may be used to target heterologous polypeptides to the Golgi apparatus by recombinantly or chemically fusing a fragment of the protein of the invention to an heterologous polypeptide. Preferred fragments are signal peptide, transmembrane domains, tyrosine containing regions and/or any other fragments of the proteins of the invention, or part thereof, that may contain (1) targeting signals for the Golgi apparatus such as the ones described in Ugur and Jones, (2000); Picetti and Borrelli, (2000), (2) tyrosine-based Golgi targeting signal region (Zhan et al., (1998); Watson and Pessin (2000); Ward and Moss (2000), or (3) any other region as defined in Munro, (1998); Luetterforst et al., (1999); Essl et al., (1999), which disclosures are hereby incorporated by reference in their entireties.

Screening and diagnosis of abnormal GENSET expression and/or biological activity

Moreover, antibodies and/or primers specific for GENSET expression may also be used to identify abnormal GENSET expression and/or biological activity, and subsequently to screen and/or diagnose disorders associated with abnormal GENSET expression. For example, a particular disease may result from lack of expression, over expression, or under expression of a GENSET mRNA. By comparing mRNA expression patterns and quantities in samples taken from healthy individuals with those from individuals suffering from a particular disorder, genes responsible for this disorder may be identified. Primers, probes and antibodies specific for this GENSET may then be used to elaborate kits of screening and diagnosis for a disorder in which the gene of interest is

specifically expressed or in which its expression is specifically dysregulated, i.e. underexpressed or overexpressed.

Screening for specific disorders

The present invention also relates to methods of identifying individuals having elevated or
5 reduced levels of GENSET, which individuals are likely to benefit from therapies to suppress or enhance GENSET expression, respectively. One example of such methods comprises the steps of:

- a) obtaining from a human or non-human mammal a biological sample;
- b) detecting the presence in said sample of a GENSET product (mRNA or protein) using
any method known to those skilled in the art including those described herein, especially at the
10 section entitled "Detection of GENSET products";
- c) comparing the amount of said GENSET product present in said sample with that of a control sample; and
- d) determining whether said human or non-human mammal has a reduced or elevated level of GENSET expression compared to the control sample.

15 Such individuals with reduced or elevated levels of GENSET products may be predisposed to disorders associated with dysregulation of GENSET gene expression and thus would be candidates for therapies. The identification of elevated levels of GENSET in a patient would be indicative of an individual that would benefit from treatment with agents that suppress GENSET expression or activity. The identification of low levels of GENSET in a patient would be indicative
20 of an individual that would benefit from agents that induce GENSET expression or activity.

Biological samples suitable for use in this method include biological fluids such as blood, lymph, saliva, sperm, maternal milk, and tissue samples (e.g. biopsies) as well as cell cultures or cell extracts derived, for example, from tissue biopsies. The detection step of the present method can be performed using standard protocols for protein/mRNA detection. Examples of suitable
25 protocols include Northern blot analysis, immunoassays (e.g. RIA, Western blots, immunohistochemical analyses), and PCR.

Thus, the present invention further relates to methods of identifying individuals or non-human animals at increased risk for developing, or present state of having, certain diseases/disorders associated with GENSET abnormal expression or biological activity. One
30 example of such methods comprises the steps of:

- a) obtaining from a human or non-human mammal a biological sample;
- b) detecting the presence or absence in said sample of a GENSET product (mRNA or protein);
- c) comparing the amount of said GENSET product present in said sample with that of a
35 control sample; and

d) determining whether said human or non-human mammal is at increased risk for developing, or present state of having, a diseases or disorder.

In accordance with this method, the presence in the sample of altered levels of GENSET product indicates that the subject is predisposed to the above-indicated diseases/disorders.

5 Biological samples suitable for use in this method include biological fluids such as blood, lymph, saliva, sperm, maternal milk, and tissue samples (e.g. biopsies).

The diagnostic methodologies described herein are applicable to both humans and non-human mammals.

Detection of GENSET mutations

10 The invention also encompasses methods to detect mutations in GENSET polynucleotides of the invention. Such methods may advantageously be used to detect mutations occurring in GENSET genes and preferably in their regulatory regions. When the mutation was proven to be associated with a disease, screening for such mutations may be used for screening and diagnosis purposes.

15 In one embodiment of the oligonucleotide arrays of the invention, an oligonucleotide probe matrix may advantageously be used to detect mutations occurring in GENSET genes and preferably in their regulatory regions. For this particular purpose, probes are specifically designed to have a nucleotide sequence allowing their hybridization to the genes that carry known mutations (either by deletion, insertion or substitution of one or several nucleotides). By known mutations, it is meant,
20 mutations on the GENSET genes that have been identified according, for example to the technique used by Huang *et al.*(1996) or Samson *et al.*(1996), which disclosures are hereby incorporated by reference in their entirety.

Another technique that is used to detect mutations in GENSET genes is the use of a high-density DNA array. Each oligonucleotide probe constituting a unit element of the high density
25 DNA array is designed to match a specific subsequence of a GENSET genomic DNA or cDNA. Thus, an array consisting of oligonucleotides complementary to subsequences of the target gene sequence is used to determine the identity of the target sequence with the wild gene sequence, measure its amount, and detect differences between the target sequence and the reference wild gene sequence of the GENSET gene. In one such design, termed 4L tiled array, is implemented a set of
30 four probes (A, C, G, T), preferably 15-nucleotide oligomers. In each set of four probes, the perfect complement will hybridize more strongly than mismatched probes. Consequently, a nucleic acid target of length L is scanned for mutations with a tiled array containing 4L probes, the whole probe set containing all the possible mutations in the known wild reference sequence. The hybridization signals of the 15-mer probe set tiled array are perturbed by a single base change in the target
35 sequence. As a consequence, there is a characteristic loss of signal or a "footprint" for the probes

flanking a mutation position. This technique was described by Chee *et al.* in 1996, which disclosure is hereby incorporated by reference in its entirety.

Construction of DNA constructs with a GENSET expression pattern

In addition, characterization of the spatial and temporal expression patterns and expression
5 levels of GENSET mRNAs is also useful for constructing expression vectors capable of producing a desired level of gene product in a desired spatial or temporal manner, as discussed below.

DNA Construct That Enables Directing Temporal And Spatial GENSET Gene Expression In Recombinant Cell Hosts And In Transgenic Animals.

In order to study the physiological and phenotypic consequences of a lack of synthesis of a
10 GENSET protein, both at the cell level and at the multi cellular organism level, the invention also encompasses DNA constructs and recombinant vectors enabling a conditional expression of a specific allele of a GENSET genomic sequence or cDNA and also of a copy of this genomic sequence or cDNA harboring substitutions, deletions, or additions of one or more bases as regards to a nucleotide sequence selected from the group consisting of sequences of SEQ ID Nos 1-241 and
15 sequences of clone inserts of the deposited clone pool, or a fragment thereof, these base substitutions, deletions or additions being located either in an exon, an intron or a regulatory sequence, but preferably in the 5'-regulatory sequence or in an exon of the GENSET genomic sequence or within the GENSET cDNA.

A first preferred DNA construct is based on the tetracycline resistance operon *tet* from *E.*
20 *coli* transposon Tn10 for controlling the GENSET gene expression, such as described by Gossen *et al.* (1992, 1995) and Furth *et al.* (1994), which disclosures are hereby incorporated by reference in their entireties. Such a DNA construct contains seven *tet* operator sequences from Tn10 (*tetop*) that are fused to either a minimal promoter or a 5'-regulatory sequence of the GENSET gene, said minimal promoter or said GENSET regulatory sequence being operably linked to a polynucleotide
25 of interest that codes either for a sense or an antisense oligonucleotide or for a polypeptide, including a GENSET polypeptide or a peptide fragment thereof. This DNA construct is functional as a conditional expression system for the nucleotide sequence of interest when the same cell also comprises a nucleotide sequence coding for either the wild type (tTA) or the mutant (rTA) repressor fused to the activating domain of viral protein VP16 of herpes simplex virus, placed under the
30 control of a promoter, such as the HCMVIE1 enhancer/promoter or the MMTV-LTR. Indeed, a preferred DNA construct of the invention comprise both the polynucleotide containing the *tet* operator sequences and the polynucleotide containing a sequence coding for the tTA or the rTA repressor. In a specific embodiment, the conditional expression DNA construct contains the sequence encoding the mutant tetracycline repressor rTA, the expression of the polynucleotide of
35 interest is silent in the absence of tetracycline and induced in its presence.

DNA Constructs Allowing Homologous Recombination: Replacement Vectors

A second preferred DNA construct will comprise, from 5'-end to 3'-end: (a) a first nucleotide sequence that is comprised in the GENSET genomic sequence; (b) a nucleotide sequence comprising a positive selection marker, such as the marker for neomycine resistance (*neo*); and (c) a second nucleotide sequence that is comprised in the GENSET genomic sequence, and is located on the genome downstream the first GENSET nucleotide sequence (a).

In a preferred embodiment, this DNA construct also comprises a negative selection marker located upstream the nucleotide sequence (a) or downstream the nucleotide sequence (c). Preferably, the negative selection marker comprises the thymidine kinase (*tk*) gene (Thomas *et al.*, 1986), the hygromycine beta gene (Te Riele *et al.*, 1990), the *hprt* gene (Van der Lugt *et al.*, 1991; Reid *et al.*, 1990) or the Diphtheria toxin A fragment (*Dt-A*) gene (Nada *et al.*, 1993; Yagi *et al.*, 1990), which disclosures are hereby incorporated by reference in their entireties. Preferably, the positive selection marker is located within a GENSET exon sequence so as to interrupt the sequence encoding a GENSET protein. These replacement vectors are described, for example, by Thomas *et al.* (1986; 1987), Mansour *et al.* (1988) and Koller *et al.* (1992).

The first and second nucleotide sequences (a) and (c) may be indifferently located within a GENSET regulatory sequence, an intronic sequence, an exon sequence or a sequence containing both regulatory and/or intronic and/or exon sequences. The size of the nucleotide sequences (a) and (c) ranges from 1 to 50 kb, preferably from 1 to 10 kb, more preferably from 2 to 6 kb and most preferably from 2 to 4 kb.

DNA Constructs Allowing Homologous Recombination: Cre-LoxP System.

These new DNA constructs make use of the site specific recombination system of the P1 phage. The P1 phage possesses a recombinase called Cre which interacts specifically with a 34 base pairs *loxP* site. The *loxP* site is composed of two palindromic sequences of 13 bp separated by a 8 bp conserved sequence (Hoess *et al.*, 1986), which disclosure is hereby incorporated by reference in its entirety. The recombination by the Cre enzyme between two *loxP* sites having an identical orientation leads to the deletion of the DNA fragment.

The Cre-*loxP* system used in combination with a homologous recombination technique has been first described by Gu *et al.* (1993, 1994), which disclosures are hereby incorporated by reference in their entireties. Briefly, a nucleotide sequence of interest to be inserted in a targeted location of the genome harbors at least two *loxP* sites in the same orientation and located at the respective ends of a nucleotide sequence to be excised from the recombinant genome. The excision event requires the presence of the recombinase (Cre) enzyme within the nucleus of the recombinant cell host. The recombinase enzyme may be brought at the desired time either by (a) incubating the recombinant cell hosts in a culture medium containing this enzyme, by injecting the Cre enzyme directly into the desired cell, such as described by Araki *et al.* (1995), which disclosure is hereby

incorporated by reference in its entirety, or by lipofection of the enzyme into the cells, such as described by Baubonis *et al.*(1993), which disclosure is hereby incorporated by reference in its entirety; (b) transfecting the cell host with a vector comprising the *Cre* coding sequence operably linked to a promoter functional in the recombinant cell host, which promoter being optionally
5 inducible, said vector being introduced in the recombinant cell host, such as described by Gu *et al.*(1993) and Sauer *et al.*(1988), which disclosures are hereby incorporated by reference in their entireties; (c) introducing in the genome of the cell host a polynucleotide comprising the *Cre* coding sequence operably linked to a promoter functional in the recombinant cell host, which promoter is optionally inducible, and said polynucleotide being inserted in the genome of the cell host either by
10 a random insertion event or an homologous recombination event, such as described by Gu *et al.*(1994).

In a specific embodiment, the vector containing the sequence to be inserted in the GENSET gene by homologous recombination is constructed in such a way that selectable markers are flanked by *loxP* sites of the same orientation, it is possible, by treatment by the *Cre* enzyme, to eliminate the
15 selectable markers while leaving the GENSET sequences of interest that have been inserted by an homologous recombination event. Again, two selectable markers are needed: a positive selection marker to select for the recombination event and a negative selection marker to select for the homologous recombination event. Vectors and methods using the *Cre-loxP* system are described by Zou *et al.*(1994), which disclosure is hereby incorporated by reference in its entirety.

20 Thus, a third preferred DNA construct of the invention comprises, from 5'-end to 3'-end: (a) a first nucleotide sequence that is comprised in the GENSET genomic sequence; (b) a nucleotide sequence comprising a polynucleotide encoding a positive selection marker, said nucleotide sequence comprising additionally two sequences defining a site recognized by a recombinase, such as a *loxP* site, the two sites being placed in the same orientation; and (c) a second nucleotide
25 sequence that is comprised in the GENSET genomic sequence, and is located on the genome downstream of the first GENSET nucleotide sequence (a).

The sequences defining a site recognized by a recombinase, such as a *loxP* site, are preferably located within the nucleotide sequence (b) at suitable locations bordering the nucleotide sequence for which the conditional excision is sought. In one specific embodiment, two *loxP* sites
30 are located at each side of the positive selection marker sequence, in order to allow its excision at a desired time after the occurrence of the homologous recombination event.

In a preferred embodiment of a method using the third DNA construct described above, the excision of the polynucleotide fragment bordered by the two sites recognized by a recombinase, preferably two *loxP* sites, is performed at a desired time, due to the presence within the genome of
35 the recombinant host cell of a sequence encoding the *Cre* enzyme operably linked to a promoter sequence, preferably an inducible promoter, more preferably a tissue-specific promoter sequence

and most preferably a promoter sequence which is both inducible and tissue-specific, such as described by Gu *et al.* (1994).

The presence of the Cre enzyme within the genome of the recombinant cell host may result from the breeding of two transgenic animals, the first transgenic animal bearing the GENSET-derived sequence of interest containing the *loxP* sites as described above and the second transgenic animal bearing the *Cre* coding sequence operably linked to a suitable promoter sequence, such as described by Gu *et al.* (1994).

Spatio-temporal control of the Cre enzyme expression may also be achieved with an adenovirus based vector that contains the Cre gene thus allowing infection of cells, or *in vivo* infection of organs, for delivery of the Cre enzyme, such as described by Anton and Graham (1995) and Kanegae *et al.* (1995), which disclosures are hereby incorporated by reference in their entireties.

The DNA constructs described above may be used to introduce a desired nucleotide sequence of the invention, preferably a GENSET genomic sequence or a GENSET cDNA sequence, and most preferably an altered copy of a GENSET genomic or cDNA sequence, within a predetermined location of the targeted genome, leading either to the generation of an altered copy of a targeted gene (knock-out homologous recombination) or to the replacement of a copy of the targeted gene by another copy sufficiently homologous to allow an homologous recombination event to occur (knock-in homologous recombination).

MODIFYING GENSET EXPRESSION AND/OR BIOLOGICAL ACTIVITY

Modifying endogenous GENSET expression and/or biological activity is expressly contemplated by the present invention.

Screening for compounds that modulate GENSET expression and/or biological activity

The present invention further relates to compounds able to modulate GENSET expression and/or biological activity and methods to use these compounds. Such compounds may interact with the regulatory sequences of GENSET genes or they may interact with GENSET polypeptides directly or indirectly.

Compounds Interacting With GENSET Regulatory Sequences

The present invention also concerns a method for screening substances or molecules that are able to interact with the regulatory sequences of a GENSET gene, such as for example promoter or enhancer sequences in untranscribed regions of the genomic DNA, as determined using any techniques known to those skilled in the art including those described in the section entitled "Identification of Promoters in Cloned Upstream Sequences, or such as regulatory sequences located in untranslated regions of GENSET mRNA.

Sequences within untranscribed or untranslated regions of polynucleotides of the invention may be identified by comparison to databases containing known regulatory sequence such as

transcription start sites, transcription factor binding sites, promoter sequences, enhancer sequences, 5'UTR and 3'UTR elements (Pesole *et al.*, 2000; <http://igs-server.cnrs-mrs.fr/~gauthere/UTR/index.html>). Alternatively, the regulatory sequences of interest may be identified through conventional mutagenesis or deletion analyses of reporter plasmids using, for instance, techniques described in the section entitled "Identification of Promoters in Cloned Upstream Sequences".

Following the identification of potential GENSET regulatory sequences, proteins which interact with these regulatory sequences may be identified as described below.

Gel retardation assays may be performed independently in order to screen candidate molecules that are able to interact with the regulatory sequences of the GENSET gene, such as described by Fried and Crothers (1981), Garner and Revzin (1981) and Dent and Latchman (1993), the teachings of these publications being herein incorporated by reference. These techniques are based on the principle according to which a DNA or mRNA fragment which is bound to a protein migrates slower than the same unbound DNA or mRNA fragment. Briefly, the target nucleotide sequence is labeled. Then the labeled target nucleotide sequence is brought into contact with either a total nuclear extract from cells containing regulation factors, or with different candidate molecules to be tested. The interaction between the target regulatory sequence of the GENSET gene and the candidate molecule or the regulation factor is detected after gel or capillary electrophoresis through a retardation in the migration.

Nucleic acids encoding proteins which are able to interact with the promoter sequence of the GENSET gene, more particularly a nucleotide sequence selected from the group consisting of the polynucleotides of the 5' and 3' regulatory region or a fragment or variant thereof, may be identified by using a one-hybrid system, such as that described in the booklet enclosed in the Matchmaker One-Hybrid System kit from Clontech (Catalog Ref. n° K1603-1), the technical teachings of which are herein incorporated by reference. Briefly, the target nucleotide sequence is cloned upstream of a selectable reporter sequence and the resulting polynucleotide construct is integrated in the yeast genome (*Saccharomyces cerevisiae*). Preferably, multiple copies of the target sequences are inserted into the reporter plasmid in tandem. The yeast cells containing the reporter sequence in their genome are then transformed with a library comprising fusion molecules between cDNAs encoding candidate proteins for binding onto the regulatory sequences of the GENSET gene and sequences encoding the activator domain of a yeast transcription factor such as GAL4. The recombinant yeast cells are plated in a culture broth for selecting cells expressing the reporter sequence. The recombinant yeast cells thus selected contain a fusion protein that is able to bind onto the target regulatory sequence of the GENSET gene. Then, the cDNAs encoding the fusion proteins are sequenced and may be cloned into expression or transcription vectors *in vitro*. The binding of the encoded polypeptides to the target regulatory sequences of the GENSET gene

may be confirmed by techniques familiar to the one skilled in the art, such as gel retardation assays or DNase protection assays.

Ligands interacting with GENSET polypeptides

For the purpose of the present invention, a ligand means a molecule, such as a protein, a peptide, an antibody or any synthetic chemical compound capable of binding to a GENSET protein or one of its fragments or variants or to modulate the expression of the polynucleotide coding for GENSET or a fragment or variant thereof.

In the ligand screening method according to the present invention, a biological sample or a defined molecule to be tested as a putative ligand of a GENSET protein is brought into contact with the corresponding purified GENSET protein, for example the corresponding purified recombinant GENSET protein produced by a recombinant cell host as described herein, in order to form a complex between this protein and the putative ligand molecule to be tested.

As an illustrative example, to study the interaction of a GENSET protein, or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384 as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool, with drugs or small molecules, such as molecules generated through combinatorial chemistry approaches, the microdialysis coupled to HPLC method described by Wang *et al.* (1997) or the affinity capillary electrophoresis method described by Bush *et al.* (1997), the disclosures of which are incorporated by reference, can be used.

In further methods, peptides, drugs, fatty acids, lipoproteins, or small molecules which interact with a GENSET protein, or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool may be identified using assays such as the following. The molecule to be tested for binding is labeled with a detectable label, such as a fluorescent, radioactive, or enzymatic tag and placed in contact with immobilized GENSET protein, or a fragment thereof under conditions which permit specific binding to occur. After removal of non-specifically bound molecules, bound molecules are detected using appropriate means.

Various candidate substances or molecules can be assayed for interaction with a GENSET polypeptide. These substances or molecules include, without being limited to, natural or synthetic organic compounds or molecules of biological origin such as polypeptides. When the candidate substance or molecule comprises a polypeptide, this polypeptide may be the resulting expression

product of a phage clone belonging to a phage-based random peptide library, or alternatively the polypeptide may be the resulting expression product of a cDNA library cloned in a vector suitable for performing a two-hybrid screening assay.

A. Candidate ligands obtained from random peptide libraries

- 5 In a particular embodiment of the screening method, the putative ligand is the expression product of a DNA insert contained in a phage vector (Parmley and Smith, 1988). Specifically, random peptide phages libraries are used. The random DNA inserts encode for peptides of 8 to 20 amino acids in length (Oldenburg *et al.*, 1992; Valadon *et al.*, 1996; Lucas, 1994; Westerink, 1995; Felici *et al.*, 1991), which disclosures are hereby incorporated by reference in their entireties.
- 10 According to this particular embodiment, the recombinant phages expressing a protein that binds to an immobilized GENSET protein is retained and the complex formed between the GENSET protein and the recombinant phage may be subsequently immunoprecipitated by a polyclonal or a monoclonal antibody directed against the GENSET protein.

- Once the ligand library in recombinant phages has been constructed, the phage population is
- 15 brought into contact with the immobilized GENSET protein. Then the preparation of complexes is washed in order to remove the non-specifically bound recombinant phages. The phages that bind specifically to the GENSET protein are then eluted by a buffer (acid pH) or immunoprecipitated by the monoclonal antibody produced by the hybridoma anti-GENSET, and this phage population is subsequently amplified by an over-infection of bacteria (for example *E. coli*). The selection step
- 20 may be repeated several times, preferably 2-4 times, in order to select the more specific recombinant phage clones. The last step comprises characterizing the peptide produced by the selected recombinant phage clones either by expression in infected bacteria and isolation, expressing the phage insert in another host-vector system, or sequencing the insert contained in the selected recombinant phages.

25 *B. Candidate ligands obtained by competition experiments.*

- Alternatively, peptides, drugs or small molecules which bind to a GENSET protein or fragment thereof comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides
- 30 included in SEQ ID Nos: 242-272 and 274-384, as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool, may be identified in competition experiments. In such assays, the GENSET protein, or a fragment thereof, is immobilized to a surface, such as a plastic plate. Increasing amounts of the peptides, drugs or small molecules are placed in contact with the immobilized GENSET protein, or a fragment thereof, in the presence of a
- 35 detectable labeled known GENSET protein ligand. For example, the GENSET ligand may be detectably labeled with a fluorescent, radioactive, or enzymatic tag. The ability of the test molecule

to bind the GENSET protein, or a fragment thereof, is determined by measuring the amount of detectably labeled known ligand bound in the presence of the test molecule. A decrease in the amount of known ligand bound to the GENSET protein, or a fragment thereof, when the test molecule is present indicated that the test molecule is able to bind to the GENSET protein, or a
5 fragment thereof.

C. Candidate ligands obtained by affinity chromatography.

Proteins or other molecules interacting with a GENSET protein, or a fragment thereof comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the
10 group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool, can also be found using affinity columns which contain the GENSET protein, or a fragment thereof. The GENSET protein, or a fragment thereof, may be attached to the column using conventional techniques including chemical coupling to a suitable
15 column matrix such as agarose, Affi Gel®, or other matrices familiar to those of skill in art. In some embodiments of this method, the affinity column contains chimeric proteins in which the GENSET protein, or a fragment thereof, is fused to glutathion S transferase (GST). A mixture of cellular proteins or pool of expressed proteins as described above is applied to the affinity column. Proteins or other molecules interacting with the GENSET protein, or a fragment thereof, attached to
20 the column can then be isolated and analyzed on 2-D electrophoresis gel as described in Ramunsen *et al.* (1997), the disclosure of which is incorporated by reference. Alternatively, the proteins retained on the affinity column can be purified by electrophoresis based methods and sequenced. The same method can be used to isolate antibodies, to screen phage display products, or to screen phage display human antibodies.

25 *D. Candidate ligands obtained by optical biosensor methods*

Proteins interacting with a GENSET protein, or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, as
30 well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool, can also be screened by using an Optical Biosensor as described in Edwards and Leatherbarrow (1997) and also in Szabo *et al.* (1995), the disclosures of which are incorporated by reference. This technique permits the detection of interactions between molecules in real time, without the need of labeled molecules. This technique is based on the surface plasmon resonance
35 (SPR) phenomenon. Briefly, the candidate ligand molecule to be tested is attached to a surface (such as a carboxymethyl dextran matrix). A light beam is directed towards the side of the surface

that does not contain the sample to be tested and is reflected by said surface. The SPR phenomenon causes a decrease in the intensity of the reflected light with a specific association of angle and wavelength. The binding of candidate ligand molecules cause a change in the refraction index on the surface, which change is detected as a change in the SPR signal. For screening of candidate
5 ligand molecules or substances that are able to interact with the GENSET protein, or a fragment thereof, the GENSET protein, or a fragment thereof, is immobilized onto a surface. This surface comprises one side of a cell through which flows the candidate molecule to be assayed. The binding of the candidate molecule on the GENSET protein, or a fragment thereof, is detected as a change of the SPR signal. The candidate molecules tested may be proteins, peptides, carbohydrates,
10 lipids, or small molecules generated by combinatorial chemistry. This technique may also be performed by immobilizing eukaryotic or prokaryotic cells or lipid vesicles exhibiting an endogenous or a recombinantly expressed GENSET protein at their surface.

The main advantage of the method is that it allows the determination of the association rate between the GENSET protein and molecules interacting with the GENSET protein. It is thus
15 possible to select specifically ligand molecules interacting with the GENSET protein, or a fragment thereof, through strong or conversely weak association constants.

E. Candidate ligands obtained through a two-hybrid screening assay.

The yeast two-hybrid system is designed to study protein-protein interactions *in vivo* (Fields and Song, 1989), which disclosure is hereby incorporated by reference in its entirety, and relies
20 upon the fusion of a bait protein to the DNA binding domain of the yeast Gal4 protein. This technique is also described in the US Patent N° US 5,667,973 and the US Patent N° 5,283,173, the technical teachings of both patents being herein incorporated by reference.

The general procedure of library screening by the two-hybrid assay may be performed as described by Harper *et al.* (1993) or as described by Cho *et al.* (1998) or also Fromont-Racine *et al.*
25 (1997), which disclosures are hereby incorporated by reference in their entireties.

The bait protein or polypeptide comprises, consists essentially of, or consists of a GENSET polypeptide or a fragment thereof comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature
30 polypeptides included in SEQ ID Nos: 242-272 and 274-384, as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool.

More precisely, the nucleotide sequence encoding the GENSET polypeptide or a fragment or variant thereof is fused to a polynucleotide encoding the DNA binding domain of the GAL4 protein, the fused nucleotide sequence being inserted in a suitable expression vector, for example
35 pAS2 or pM3.

Then, a human cDNA library is constructed in a specially designed vector, such that the human cDNA insert is fused to a nucleotide sequence in the vector that encodes the transcriptional domain of the GAL4 protein. Preferably, the vector used is the pACT vector. The polypeptides encoded by the nucleotide inserts of the human cDNA library are termed "pray" polypeptides.

- 5 A third vector contains a detectable marker gene, such as beta galactosidase gene or CAT gene that is placed under the control of a regulation sequence that is responsive to the binding of a complete Gal4 protein containing both the transcriptional activation domain and the DNA binding domain. For example, the vector pG5EC may be used.

Two different yeast strains are also used. As an illustrative but non limiting example the
10 two different yeast strains may be the followings :

- Y190, the phenotype of which is (MATa, Leu2-3, 112 ura3-12, trp1-901, his3-D200, ade2-101, gal4Dgal180D URA3 GAL-LacZ, LYS GAL-HIS3, cyh^r);
- Y187, the phenotype of which is (MATa gal4 gal80 his3 trp1-901 ade2-101 ura3-52 leu2-3, -112 URA3 GAL-lacZmet^r), which is the opposite mating type of Y190.

- 15 Briefly, 20 µg of pAS2/GENSET and 20 µg of pACT-cDNA library are co-transformed into yeast strain Y190. The transformants are selected for growth on minimal media lacking histidine, leucine and tryptophan, but containing the histidine synthesis inhibitor 3-AT (50 mM). Positive colonies are screened for beta galactosidase by filter lift assay. The double positive colonies (His⁺, beta-gal⁺) are then grown on plates lacking histidine, leucine, but containing
20 tryptophan and cycloheximide (10 mg/ml) to select for loss of pAS2/GENSET plasmids but retention of pACT-cDNA library plasmids. The resulting Y190 strains are mated with Y187 strains expressing GENSET or non-related control proteins; such as cyclophilin B, lamin, or SNF1, as Gal4 fusions as described by Harper *et al.* (1993) and by Bram *et al.* (1993), which disclosures are hereby incorporated by reference in their entireties, and screened for beta galactosidase by filter lift assay.
25 Yeast clones that are beta gal- after mating with the control Gal4 fusions are considered false positives.

- In another embodiment of the two-hybrid method according to the invention, interaction between the GENSET or a fragment or variant thereof with cellular proteins may be assessed using the Matchmaker Two Hybrid System 2 (Catalog No. K1604-1, Clontech). As described in the
30 manual accompanying the kit, the disclosure of which is incorporated herein by reference, nucleic acids encoding the GENSET protein or a portion thereof, are inserted into an expression vector such that they are in frame with DNA encoding the DNA binding domain of the yeast transcriptional activator GAL4. A desired cDNA, preferably human cDNA, is inserted into a second expression vector such that they are in frame with DNA encoding the activation domain of GAL4. The two
35 expression plasmids are transformed into yeast and the yeast are plated on selection medium which selects for expression of selectable markers on each of the expression vectors as well as GAL4 dependent expression of the HIS3 gene. Transformants capable of growing on medium lacking

histidine are screened for GAL4 dependent lacZ expression. Those cells which are positive in both the histidine selection and the lacZ assay contain interaction between GENSET and the protein or peptide encoded by the initially selected cDNA insert.

Compounds Modulating GENSET biological activity

5 Another method of screening for compounds that modulate GENSET gene expression and/or biological activity is by measuring the effects of test compounds on a given cellular property in a host cell, such as apoptosis, proliferation, differentiation, protein glycosylation, etc... using a variety of techniques known to those skilled in the art including those described herein and especially in the section entitled “**Erreur! Source du renvoi introuvable.**”.

10 In one embodiment, the present invention relates to a method of identifying an agent which alters GENSET activity, wherein a nucleic acid construct comprising a nucleic acid which encodes a mammalian GENSET polypeptide is introduced into a host cell. The host cells produced are maintained under conditions appropriate for expression of the encoded mammalian GENSET polypeptides, whereby the nucleic acid is expressed. The host cells are then contacted with a
15 compound to be assessed (an agent) and the given cellular property of the cells is detected in the presence of the compound to be assessed. Detection of a change in the given cellular property in the presence of the agent indicates that the agent alters GENSET activity.

 In a particular embodiment, the invention relates to a method of identifying an agent which is an activator of GENSET activity, wherein detection of a change of the given cellular property in
20 the presence of the agent indicates that the agent activates GENSET activity. In another particular embodiment, the invention relates to a method of identifying an agent which is an inhibitor of GENSET activity, wherein detection of a change of the given cellular property in the presence of the agent indicates that the agent inhibits GENSET activity.

Methods of Screening for Compounds Modulating GENSET Expression and/or Activity

25 The present invention also relates to methods of screening compounds for their ability to modulate (e.g. increase or inhibit) the activity or expression of GENSET. More specifically, the present invention relates to methods of testing compounds for their ability either to increase or to decrease expression or activity of GENSET. The assays are performed *in vitro* or *in vivo*.

In vitro methods

30 *In vitro*, cells expressing GENSET are incubated in the presence and absence of the test compound. By determining the level of GENSET expression in the presence of the test compound or the level of GENSET activity in the presence of the test compound, compounds can be identified that suppress or enhance GENSET expression or activity. Alternatively, constructs comprising a GENSET regulatory sequence operably linked to a reporter gene (e.g. luciferase, chloramphenicol
35 acetyl transferase, LacZ, green fluorescent protein, etc.) can be introduced into host cells and the

effect of the test compounds on expression of the reporter gene detected. Cells suitable for use in the foregoing assays include, but are not limited to, cells having the same origin as tissues or cell lines in which the polypeptide is known to be expressed using the data from Table IX.

Consequently, the present invention encompasses a method for screening molecules that
5 modulate the expression of a GENSET gene, said screening method comprising the steps of:

- a) cultivating a prokaryotic or an eukaryotic cell that has been transfected with a nucleotide sequence encoding a GENSET protein or a variant or a fragment thereof, placed under the control of its own promoter;
- b) bringing into contact said cultivated cell with a molecule to be tested;
- 10 c) quantifying the expression of said GENSET protein or a variant or a fragment thereof in the presence of said molecule.

Using DNA recombination techniques well known by the one skill in the art, the GENSET protein encoding DNA sequence is inserted into an expression vector, downstream from its promoter sequence. As an illustrative example, the promoter sequence of the GENSET gene is
15 contained in the 5' untranscribed region of the GENSET genomic DNA.

The quantification of the expression of a GENSET protein may be realized either at the mRNA level (using for example Northern blots, RT-PCR, preferably quantitative RT-PCR with primers and probes specific for the GENSET mRNA of interest) or at the protein level (using polyclonal or monoclonal antibodies in immunoassays such as ELISA or RIA assays, Western blots,
20 or immunochemistry).

The present invention also concerns a method for screening substances or molecules that are able to increase, or in contrast to decrease, the level of expression of a GENSET gene. Such a method may allow the one skilled in the art to select substances exerting a regulating effect on the expression level of a GENSET gene and which may be useful as active ingredients included in
25 pharmaceutical compositions for treating patients suffering from disorders associated with abnormal levels of GENSET products.

Thus, also part of the present invention is a method for screening a candidate molecule that modulates the expression of a GENSET gene, this method comprises the following steps:

- a) providing a recombinant cell host containing a nucleic acid, wherein said nucleic acid
30 comprises a GENSET 5' regulatory region or a regulatory active fragment or variant thereof, operably linked to a polynucleotide encoding a detectable protein;
- b) obtaining a candidate molecule; and
- c) determining the ability of said candidate molecule to modulate the expression levels of said polynucleotide encoding the detectable protein.

35 In a further embodiment, said nucleic acid comprising a GENSET 5' regulatory region or a regulatory active fragment or variant thereof, includes the 5'UTR region of a GENSET cDNA selected from the group comprising of the 5'UTRs of the sequences of SEQ ID Nos 1-241,

sequences of clones inserts of the deposited clone pool, regulatory active fragments and variants thereof. In a more preferred embodiment of the above screening method, said nucleic acid includes a promoter sequence which is endogenous with respect to the GENSET 5'UTR sequence. In another more preferred embodiment of the above screening method, said nucleic acid includes a promoter sequence which is exogenous with respect to the GENSET 5'UTR sequence defined therein.

Preferred polynucleotides encoding a detectable protein are polynucleotides encoding beta galactosidase, green fluorescent protein (GFP) and chloramphenicol acetyl transferase (CAT).

The invention further relates to a method for the production of a pharmaceutical composition comprising a method of screening a candidate molecule that modulates the expression of a GENSET gene and furthermore mixing the identified molecule with a pharmaceutically acceptable carrier.

The invention also pertains to kits for the screening of a candidate substance modulating the expression of a GENSET gene. Preferably, such kits comprise a recombinant vector that allows the expression of a GENSET 5' regulatory region or a regulatory active fragment or a variant thereof, operably linked to a polynucleotide encoding a detectable protein or a GENSET protein or a fragment or a variant thereof. More preferably, such kits include a recombinant vector that comprises a nucleic acid including the 5'UTR region of a GENSET cDNA selected from the group comprising the 5'UTRs of the sequences of SEQ ID Nos 1-241, sequences of clones inserts of the deposited clone pool, regulatory active fragments and variants thereof, being operably linked to a polynucleotide encoding a detectable protein.

For the design of suitable recombinant vectors useful for performing the screening methods described above, it will be referred to the section of the present specification wherein the preferred recombinant vectors of the invention are detailed.

Another object of the present invention comprises methods and kits for the screening of candidate substances that interact with a GENSET polypeptide, fragments or variants thereof. By their capacity to bind covalently or non-covalently to a GENSET protein, fragments or variants thereof, these substances or molecules may be advantageously used both *in vitro* and *in vivo*.

In vitro, said interacting molecules may be used as detection means in order to identify the presence of a GENSET protein in a sample, preferably a biological sample.

A method for the screening of a candidate substance that interact with a GENSET polypeptide, fragments or variants thereof, said methods comprising the following steps:

a) providing a polypeptide comprising, consisting essentially of, or consisting of a GENSET protein or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides

included in SEQ ID Nos: 242-272 and 274-384 as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool;

- b) obtaining a candidate substance;
- c) bringing into contact said polypeptide with said candidate substance;
- 5 d) detecting the complexes formed between said polypeptide and said candidate substance.

The invention further relates to a method for the production of a pharmaceutical composition comprising a method for the screening of a candidate substance that interact with a GENSET polypeptide, fragments or variants thereof and furthermore mixing the identified substance with a pharmaceutically acceptable carrier.

- 10 The invention further concerns a kit for the screening of a candidate substance interacting with the GENSET polypeptide, wherein said kit comprises:

- a) a polypeptide comprising, consisting essentially of, or consisting of a GENSET protein or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide
- 15 selected from the group consisting of sequences of SEQ ID Nos: 242-482, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384 as well as full-length and mature polypeptides encoded by the clone inserts of the deposited clone pool; and
- b) optionally means useful to detect the complex formed between said polypeptide or a variant thereof and the candidate substance.

- 20 In a preferred embodiment of the kit described above, the detection means comprises a monoclonal or polyclonal antibody binding to said GENSET protein or fragment or variant thereof.

In vivo methods

- Compounds that suppress or enhance GENSET expression can also be identified using *in vivo* screens. In these assays, the test compound is administered (e.g. IV, IP, IM, orally, or
- 25 otherwise), to the animal, for example, at a variety of dose levels. The effect of the compound on GENSET expression is determined by comparing GENSET levels, for example in tissues known to express the gene of interest using, for example the data obtained in Table IX, and using Northern blots, immunoassays, PCR, etc., as described above. Suitable test animals include rodents (e.g., mice and rats), primates, mammals. Humanized mice can also be used as test animals, that is mice
- 30 in which the endogenous mouse protein is ablated (knocked out) and the homologous human protein added back by standard transgenic approaches. Such mice express only the human form of a protein. Humanized mice expressing only the human GENSET can be used to study *in vivo* responses to potential agents regulating GENSET protein or mRNA levels. As an example, transgenic mice have been produced carrying the human apoE4 gene. They are then bred with a
- 35 mouse line that lacks endogenous apoE, to produce an animal model carrying human proteins believed to be instrumental in development of Alzheimer's pathology. Such transgenic animals are useful for dissecting the biochemical and physiological steps of disease, and for development of

therapies for disease intervention (Loring, *et al*, 1996) (incorporated herein by reference in its entirety).

Uses for compounds modulating GENSET expression and/or biological activity

Using *in vivo* (or *in vitro*) systems, it may be possible to identify compounds that exert a
5 tissue specific effect, for example, that increase GENSET expression or activity only in tissues of
interest. Screening procedures such as those described above are also useful for identifying agents
for their potential use in pharmacological intervention strategies. Agents that enhance GENSET
expression or stimulate its activity may thus be used to treat disorders which require upregulated
levels of GENSET gene expression and/or activity. Compounds that suppress GENSET expression
10 or inhibit its activity can be used to treat disorders which require downregulated levels of GENSET
gene expression and/or activity.

Also encompassed by the present invention is an agent which interacts with GENSET
directly or indirectly, and inhibits or enhances GENSET expression and/or function. In one
embodiment, the agent is an inhibitor which interferes with GENSET directly (e.g., by binding
15 GENSET) or indirectly (e.g., by blocking the ability of GENSET to have a GENSET biological
activity). In a particular embodiment, an inhibitor of GENSET protein is an antibody specific for
GENSET protein or a functional portion of GENSET; that is, the antibody binds a GENSET
polypeptide. For example, the antibody can be specific for a polypeptide encoded by one of the
amino acid sequences of human GENSET genes (SEQ ID Nos: 242-482, mature polypeptides
20 included in SEQ ID Nos: 242-272 and 274-384, full-length and mature polypeptides encoded by the
clone inserts of the deposited clone pool), mammal GENSET or portions thereof. Alternatively, the
inhibitor can be an agent other than an antibody (e.g., small organic molecule, protein or peptide)
which binds GENSET and blocks its activity. For example, the inhibitor can be an agent which
mimics GENSET structurally, but lacks its function. Alternatively, it can be an agent which binds
25 to or interacts with a molecule which GENSET normally binds with or interacts with, thus blocking
GENSET from doing so and preventing it from exerting the effects it would normally exert.

In another embodiment, the agent is an enhancer (activator) of GENSET which increases
the activity of GENSET (increases the effect of a given amount or level of GENSET), increases the
length of time it is effective (by preventing its degradation or otherwise prolonging the time during
30 which it is active) or both either directly or indirectly.

The GENSET sequences of the present invention can also be used to generate nonhuman
gene knockout animals, such as mice, which lack a GENSET gene or transgenically overexpress
GENSET. For example, such GENSET gene knockout mice can be generated and used to obtain
further insight into the function of GENSET as well as assess the specificity of GENSET activators
35 and inhibitors. Also, over expression of GENSET (e.g., human GENSET) in transgenic mice can
be used as a means of creating a test system for GENSET activators and inhibitors (e.g., against

human GENSET). In addition, the GENSET gene can be used to clone the GENSET promoter/enhancer in order to identify regulators of GENSET transcription. GENSET gene knockout animals include animals which completely or partially lack the GENSET gene and/or GENSET activity or function. Thus the present invention relates to a method of inhibiting (partially
5 or completely) GENSET biological activity in a mammal (e.g., human) comprising administering to the mammal an effective amount of an inhibitor of GENSET. The invention also relates to a method of enhancing GENSET biological activity in a mammal comprising administering to the mammal an effective amount of an enhancer GENSET.

Inhibiting GENSET expression

10 Therapeutic compositions according to the present invention may comprise advantageously one or several GENSET oligonucleotide fragments as an antisense tool or a triple helix tool that inhibits the expression of the corresponding GENSET gene.

Antisense Approach

In antisense approaches, nucleic acid sequences complementary to an mRNA are hybridized
15 to the mRNA intracellularly, thereby blocking the expression of the protein encoded by the mRNA. The antisense nucleic acid molecules to be used in gene therapy may be either DNA or RNA sequences. Preferred methods using antisense polynucleotide according to the present invention are the procedures described by Sczakiel *et al.*(1995), which disclosure is hereby incorporated by reference in its entirety.

20 Preferably, the antisense tools are chosen among the polynucleotides (15-200 bp long) that are complementary to GENSET mRNA, more preferably to the 5' end of the GENSET mRNA. In another embodiment, a combination of different antisense polynucleotides complementary to different parts of the desired targeted gene are used.

Other preferred antisense polynucleotides according to the present invention are sequences
25 complementary to either a sequence of GENSET mRNAs comprising the translation initiation codon ATG or a sequence of GENSET genomic DNA containing a splicing donor or acceptor site.

Preferably, the antisense polynucleotides of the invention have a 3' polyadenylation signal that has been replaced with a self-cleaving ribozyme sequence, such that RNA polymerase II transcripts are produced without poly(A) at their 3' ends, these antisense polynucleotides being
30 incapable of export from the nucleus, such as described by Liu *et al.*(1994), which disclosure is hereby incorporated by reference in its entirety. In a preferred embodiment, these GENSET antisense polynucleotides also comprise, within the ribozyme cassette, a histone stem-loop structure to stabilize cleaved transcripts against 3'-5' exonucleolytic degradation, such as the structure described by Eckner *et al.*(1991), which disclosure is hereby incorporated by reference in its
35 entirety.

The antisense nucleic acids should have a length and melting temperature sufficient to permit formation of an intracellular duplex having sufficient stability to inhibit the expression of the GENSET mRNA in the duplex. Strategies for designing antisense nucleic acids suitable for use in gene therapy are disclosed in Green *et al.*, (1986) and Izant and Weintraub, (1984), the disclosures of which are incorporated herein by reference.

In some strategies, antisense molecules are obtained by reversing the orientation of the GENSET coding region with respect to a promoter so as to transcribe the opposite strand from that which is normally transcribed in the cell. The antisense molecules may be transcribed using *in vitro* transcription systems such as those which employ T7 or SP6 polymerase to generate the transcript.

10 Another approach involves transcription of GENSET antisense nucleic acids *in vivo* by operably linking DNA containing the antisense sequence to a promoter in a suitable expression vector.

Alternatively, oligonucleotides which are complementary to the strand normally transcribed in the cell may be synthesized *in vitro*. Thus, the antisense nucleic acids are complementary to the corresponding mRNA and are capable of hybridizing to the mRNA to create a duplex. In some

15 embodiments, the antisense sequences may contain modified sugar phosphate backbones to increase stability and make them less sensitive to RNase activity. Examples of modifications suitable for use in antisense strategies include 2' O-methyl RNA oligonucleotides and Protein-nucleic acid (PNA) oligonucleotides. Further examples are described by Rossi *et al.*, (1991), which disclosure is hereby incorporated by reference in its entirety.

20 Various types of antisense oligonucleotides complementary to the sequence of the GENSET cDNA or genomic DNA may be used. In one preferred embodiment, stable and semi-stable antisense oligonucleotides described in International Application No. PCT WO94/23026, hereby incorporated by reference, are used. In these molecules, the 3' end or both the 3' and 5' ends are engaged in intramolecular hydrogen bonding between complementary base pairs. These molecules

25 are better able to withstand exonuclease attacks and exhibit increased stability compared to conventional antisense oligonucleotides.

In another preferred embodiment, the antisense oligodeoxynucleotides against herpes simplex virus types 1 and 2 described in International Application No. WO 95/04141, hereby incorporated by reference, are used.

30 In yet another preferred embodiment, the covalently cross-linked antisense oligonucleotides described in International Application No. WO 96/31523, hereby incorporated by reference, are used. These double- or single-stranded oligonucleotides comprise one or more, respectively, inter- or intra-oligonucleotide covalent cross-linkages, wherein the linkage consists of an amide bond between a primary amine group of one strand and a carboxyl group of the other strand or of the

35 same strand, respectively, the primary amine group being directly substituted in the 2' position of the strand nucleotide monosaccharide ring, and the carboxyl group being carried by an aliphatic

spacer group substituted on a nucleotide or nucleotide analog of the other strand or the same strand, respectively.

The antisense oligodeoxynucleotides and oligonucleotides disclosed in International Application No. WO 92/18522, incorporated by reference, may also be used. These molecules are
5 stable to degradation and contain at least one transcription control recognition sequence which binds to control proteins and are effective as decoys therefor. These molecules may contain "hairpin" structures, "dumbbell" structures, "modified dumbbell" structures, "cross-linked" decoy structures and "loop" structures.

In another preferred embodiment, the cyclic double-stranded oligonucleotides described in
10 European Patent Application No. 0 572 287 A2, hereby incorporated by reference are used. These ligated oligonucleotide "dumbbells" contain the binding site for a transcription factor and inhibit expression of the gene under control of the transcription factor by sequestering the factor.

Use of the closed antisense oligonucleotides disclosed in International Application No. WO 92/19732, hereby incorporated by reference, is also contemplated. Because these molecules have
15 no free ends, they are more resistant to degradation by exonucleases than are conventional oligonucleotides. These oligonucleotides may be multifunctional, interacting with several regions which are not adjacent to the target mRNA.

The appropriate level of antisense nucleic acids required to inhibit gene expression may be determined using *in vitro* expression analysis. The antisense molecule may be introduced into the
20 cells by diffusion, injection, infection or transfection using procedures known in the art. For example, the antisense nucleic acids can be introduced into the body as a bare or naked oligonucleotide, oligonucleotide encapsulated in lipid, oligonucleotide sequence encapsidated by viral protein, or as an oligonucleotide operably linked to a promoter contained in an expression vector. The expression vector may be any of a variety of expression vectors known in the art,
25 including retroviral or viral vectors, vectors capable of extrachromosomal replication, or integrating vectors. The vectors may be DNA or RNA.

The antisense molecules are introduced onto cell samples at a number of different concentrations preferably between 1×10^{-10} M to 1×10^{-4} M. Once the minimum concentration that can adequately control gene expression is identified, the optimized dose is translated into a dosage
30 suitable for use *in vivo*. For example, an inhibiting concentration in culture of 1×10^{-7} translates into a dose of approximately 0.6 mg/kg bodyweight. Levels of oligonucleotide approaching 100 mg/kg bodyweight or higher may be possible after testing the toxicity of the oligonucleotide in laboratory animals. It is additionally contemplated that cells from the vertebrate are removed, treated with the antisense oligonucleotide, and reintroduced into the vertebrate.

35 In a preferred application of this invention, the polypeptide encoded by the gene is first identified, so that the effectiveness of antisense inhibition on translation can be monitored using

techniques that include but are not limited to antibody-mediated tests such as RIAs and ELISA, functional assays, or radiolabeling.

An alternative to the antisense technology that is used according to the present invention comprises using ribozymes that will bind to a target sequence via their complementary
5 polynucleotide tail and that will cleave the corresponding RNA by hydrolyzing its target site (namely "hammerhead ribozymes"). Briefly, the simplified cycle of a hammerhead ribozyme comprises (1) sequence specific binding to the target RNA via complementary antisense sequences; (2) site-specific hydrolysis of the cleavable motif of the target strand; and (3) release of cleavage products, which gives rise to another catalytic cycle. Indeed, the use of long-chain antisense
10 polynucleotide (at least 30 bases long) or ribozymes with long antisense arms are advantageous. A preferred delivery system for antisense ribozyme is achieved by covalently linking these antisense ribozymes to lipophilic groups or to use liposomes as a convenient vector. Preferred antisense ribozymes according to the present invention are prepared as described by Rossi *et al.*, (1991) and Sczakiel *et al.* (1995), the specific preparation procedures being referred to in said articles being
15 herein incorporated by reference.

Triple Helix Approach

The GENSET genomic DNA may also be used to inhibit the expression of the GENSET gene based on intracellular triple helix formation.

Triple helix oligonucleotides are used to inhibit transcription from a genome. They are
20 particularly useful for studying alterations in cell activity when it is associated with a particular gene. The GENSET cDNAs or genomic DNAs of the present invention or, more preferably, a fragment of those sequences, can be used to inhibit gene expression in individuals having diseases associated with expression of a particular gene. Similarly, a portion of the GENSET genomic DNA can be used to study the effect of inhibiting GENSET transcription within a cell. Traditionally,
25 homopurine sequences were considered the most useful for triple helix strategies. However, homopyrimidine sequences can also inhibit gene expression. Such homopyrimidine oligonucleotides bind to the major groove at homopurine:homopyrimidine sequences. Thus, both types of sequences from the GENSET genomic DNA are contemplated within the scope of this invention.

30 To carry out gene therapy strategies using the triple helix approach, the sequences of the GENSET genomic DNA are first scanned to identify 10-mer to 20-mer homopyrimidine or homopurine stretches which could be used in triple-helix based strategies for inhibiting GENSET expression. Following identification of candidate homopyrimidine or homopurine stretches, their efficiency in inhibiting GENSET expression is assessed by introducing varying amounts of
35 oligonucleotides containing the candidate sequences into tissue culture cells which express the GENSET gene.

The oligonucleotides can be introduced into the cells using a variety of methods known to those skilled in the art, including but not limited to calcium phosphate precipitation, DEAE-Dextran, electroporation, liposome-mediated transfection or native uptake.

Treated cells are monitored for altered cell function or reduced GENSET expression using techniques such as Northern blotting, RNase protection assays, or PCR based strategies to monitor the transcription levels of the GENSET gene in cells which have been treated with the oligonucleotide. The cell functions to be monitored are predicted based upon the homologies of the target gene corresponding to the cDNA from which the oligonucleotide was derived with known gene sequences that have been associated with a particular function. The cell functions can also be predicted based on the presence of abnormal physiology within cells derived from individuals with a particular inherited disease, particularly when the cDNA is associated with the disease using techniques described in the section entitled "Identification of genes associated with hereditary diseases or drug response".

The oligonucleotides which are effective in inhibiting gene expression in tissue culture cells may then be introduced *in vivo* using the techniques and at a dosage calculated based on the *in vitro* results, as described in the section entitled "Antisense Approach".

In some embodiments, the natural (beta) anomers of the oligonucleotide units can be replaced with alpha anomers to render the oligonucleotide more resistant to nucleases. Further, an intercalating agent such as ethidium bromide, or the like, can be attached to the 3' end of the alpha oligonucleotide to stabilize the triple helix. For information on the generation of oligonucleotides suitable for triple helix formation see Griffin *et al.* (1989), which is hereby incorporated by this reference.

Treating GENSET-related disorders

The present invention further relates to methods of treating diseases/disorders by increasing GENSET activity and/or expression. The invention also relates to methods of treating diseases/disorders by decreasing GENSET activity and or expression. These methodologies can be effected using compounds selected using screening protocols such as those described herein and/or by using the gene therapy and antisense approaches described in the art and herein. Gene therapy can be used to effect targeted expression of GENSET. The GENSET coding sequence can be cloned into an appropriate expression vector and targeted to a particular cell type(s) to achieve efficient, high level expression. Introduction of the GENSET coding sequence into target cells can be achieved, for example, using particle mediated DNA delivery, (Haynes, 1996 and Maurer, 1999), direct injection of naked DNA, (Levy *et al.*, 1996; and Felgner, 1996), or viral vector mediated transport (Smith *et al.*, 1996, Stone *et al.*, 2000; Wu and Atai, 2000), each of which disclosures are hereby incorporated by reference in their entireties. Tissue specific effects can be achieved, for

example, in the case of virus mediated transport by using viral vectors that are tissue specific, or by the use of promoters that are tissue specific.

Combinatorial approaches can also be used to ensure that the GENSET coding sequence is activated in the target tissue (Butt and Karathanasis, 1995; Miller and Whelan, 1997), which disclosures are hereby incorporated by reference in their entireties. Antisense oligonucleotides complementary to GENSET mRNA can be used to selectively diminish or ablate the expression of the protein, for example, at sites of inflammation. More specifically, antisense constructs or antisense oligonucleotides can be used to inhibit the production of GENSET in high expressing cells such as those cited in the third column of Table X. Antisense mRNA can be produced by transfecting into target cells an expression vector with the GENSET gene sequence, or portion thereof, oriented in an antisense direction relative to the direction of transcription. Appropriate vectors include viral vectors, including retroviral, adenoviral, and adeno-associated viral vectors, as well as nonviral vectors. Tissue specific promoters can be used. Alternatively, antisense oligonucleotides can be introduced directly into target cells to achieve the same goal. (See also other delivery methodologies described herein in connection with gene therapy.). Oligonucleotides can be selected/designed to achieve a high level of specificity (Wagner *et al.*, 1996), which disclosure is hereby incorporated by reference in its entirety. The therapeutic methodologies described herein are applicable to both human and non-human mammals (including cats and dogs).

PHARMACEUTICAL AND PHYSIOLOGICALLY ACCEPTABLE COMPOSITIONS

The present invention also relates to pharmaceutical or physiologically acceptable compositions comprising, as active agent, the polypeptides, nucleic acids or antibodies of the invention. The invention also relates to compositions comprising, as active agent, compounds selected using the above-described screening protocols. Such compositions include the active agent in combination with a pharmaceutical or physiologically acceptably acceptable carrier. In the case of naked DNA, the "carrier" may be gold particles. The amount of active agent in the composition can vary with the agent, the patient and the effect sought. Likewise, the dosing regimen can vary depending on the composition and the disease/disorder to be treated.

Therefore, the invention related to methods for the production of pharmaceutical composition comprising a method for selecting an active agent, compound, substance or molecule using any of the screening method described herein and furthermore mixing the identified active agent, compound, substance or molecule with a pharmaceutically acceptable carrier.

The pharmaceutical compositions utilized in this invention may be administered by any number of routes including, but not limited to, oral, intravenous, intramuscular, intra-arterial, intramedullary, intrathecal, intraventricular, transdermal, subcutaneous, intraperitoneal, intranasal, enteral, topical, sublingual, or rectal means. In addition to the active ingredients, these pharmaceutical compositions may contain suitable pharmaceutically acceptable carriers comprising

excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. Further details on techniques for formulation and administration may be found in the latest edition of Remington's Pharmaceutical Sciences (Maack PublishingCo. Easton, Pa).

5 Pharmaceutical compositions for oral administration can be formulated using pharmaceutically acceptable carriers well known in the art in dosages suitable for oral administration. Such carriers enable the pharmaceutical compositions to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions, and the like, for ingestion by the patient.

10 Pharmaceutical preparations for oral use can be obtained through a combination of active compounds with solid excipient, suiting mixture is optionally grinding, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients are carbohydrate or protein fillers, such as sugars, including lactose, sucrose, mannitol, or sorbitol; starch from corn, wheat, rice, potato, or other plants; cellulose, such as methyl cellulose, 15 hydroxypropylmethyl-cellulose, or sodium carboxymethylcellulose; gums including arabic and tragacanth; and proteins such as gelatin and collagen. If desired, disintegrating or solubilizing agents may be added, such as the cross-linked polyvinyl pyrrolidone, agar, alginic acid, or a salt thereof, such as sodium alginate.

 Dragee cores may be used in conjunction with suitable coatings, such as concentrated sugar 20 solutions, which may also contain gum arabic, talc, polyvinylpyrrolidone, carbopol gel, polyethylene glycol, and/or titaniumdioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for product identification or to characterize the quantity of active compound, i.e., dosage.

 Pharmaceutical preparations which can be used orally include push-fit capsules made of 25 gelatin, as well as soft, sealed capsules made of gelatin and a coating, such as glycerol or sorbitol. Push-fit capsules can contain active ingredients mixed with a filler or binders, such as lactose or starches, lubricants, such as talc or magnesium stearate, and, optionally, stabilizers. In soft capsules, the active compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid, or liquidpolyethylene glycol with or without stabilizers.

30 Pharmaceutical formulations suitable for parenteral administration may be formulated in aqueous solutions, preferably in physiologically compatible buffers such as Hanks solution, Ringer's solution, or physiologically buffered saline. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethylcellulose, sorbitol, or dextran. Additionally, suspensions of the active compounds may be prepared as 35 appropriate oily injection suspensions. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes.

Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

For topical or nasal administration, penetrants appropriate to the particular barrier to be permeated are used in the formulation. Such penetrants are generally known in the art.

5 The pharmaceutical compositions of the present invention may be manufactured in a manner that is known in the art, e.g., by means of conventional mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping, or lyophilizing processes.

The pharmaceutical composition may be provided as a salt and can be formed with many acids, including but not limited to, hydrochloric, sulfuric, acetic, lactic, tartaric, malic, succinic, etc.

10 Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free base forms. In other cases, the preferred preparation may be a lyophilized powder which may contain any or all of the following: 1-50 mM histidine, 0.1%-2% sucrose, and 2-7% mannitol, at a pH range of 4.5 to 5.5, that is combined with buffer prior to use.

After pharmaceutical compositions have been prepared, they can be placed in an
15 appropriate container and labeled for treatment of an indicated condition. For administration of GENSET, such labeling would include amount, frequency, and method of administration.

Pharmaceutical compositions suitable for use in the invention include compositions wherein the active ingredients are contained in an effective amount to achieve the intended purpose. The determination of an effective dose is well within the capability of those skilled in the art.

20 For any compound, the therapeutically effective dose can be estimated initially either in cell culture assays, e.g., of neoplastic cells, or in animal models, usually mice, rabbits, dogs, or pigs. The animal model may also be used to determine the appropriate concentration range and route of administration. Such information can then be used to determine useful doses and routes for administration in humans.

25 A therapeutically effective dose refers to that amount of active ingredient, for example GENSET or fragments thereof, antibodies of GENSET, agonists, antagonists or inhibitors of GENSET, which ameliorates the symptoms or condition. Therapeutic efficacy and toxicity may be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., ED₅₀ (the dose therapeutically effective in 50% of the population) and LD₅₀ (the dose lethal to
30 50% of the population). The dose ratio between therapeutic and toxic effects is the therapeutic index, and it can be expressed as the ratio, LD₅₀/ED₅₀. Pharmaceutical compositions which exhibit large therapeutic indices are preferred. The data obtained from cell culture assays and animal studies is used in formulating a range of dosage for human use. The dosage contained in such compositions is preferably within a range of circulating concentrations that include the ED₅₀
35 with little or no toxicity. The dosage varies within this range depending upon the dosage form employed, sensitivity of the patient, and the route of administration.

The exact dosage will be determined by the practitioner, in light of factors related to the subject that requires treatment. Dosage and administration are adjusted to provide sufficient levels of the active moiety or to maintain the desired effect. Factors which may be taken into account include the severity of the disease state, general health of the subject, age, weight, and gender of the subject, diet, time and frequency of administration, drug combination(s), reaction sensitivities, and tolerance/response to therapy. Long-acting pharmaceutical compositions may be administered every 3 to 4 days, every week, or once every two weeks depending on half-life and clearance rate of the particular formulation.

Normal dosage amounts may vary from 0.1 to 100,000 micrograms, up to a total dose of about 1 g, depending upon the route of administration. Guidance as to particular dosages and methods of delivery is provided in the literature and generally available to practitioners in the art. Those skilled in the art will employ different formulations for nucleotides than for proteins or their inhibitors. Similarly, delivery of polynucleotides or polypeptides will be specific to particular cells, conditions, locations, etc.

15 **USES OF GENSET SEQUENCES: COMPUTER-RELATED EMBODIMENTS**

As used herein the term “cDNA codes of SEQ ID Nos: 1-241” encompasses the nucleotide sequences of SEQ ID Nos: 1-241 and of clones inserts of the deposited clone pool, fragments thereof, nucleotide sequences homologous thereto, and sequences complementary to all of the preceding sequences. The fragments include fragments of SEQ ID Nos: 1-241 comprising at least 8, 10, 12, 15, 18, 20, 25, 28, 30, 35, 40, 50, 75, 100, 150, 200, 300, 400, 500, 1000 or 2000 consecutive nucleotides of SEQ ID Nos: 1-241. Preferably the fragments include signal sequences and coding sequences for mature polypeptides of SEQ ID Nos: 1-31 and 33-143, polynucleotides described in Tables Va and Table Vb, polynucleotides encoding polypeptides described in Table VI, polynucleotide described herein as encoding polypeptides having a biological activity, or fragments comprising at least 8, 10, 12, 15, 18, 20, 25, 28, 30, 35, 40, 50, 75, 100, 150, 200, 300, 400, 500, 1000 or 2000 consecutive nucleotides of the signal sequences or coding sequences for mature polypeptides of SEQ ID Nos: 1-31 and 33-143, polynucleotides described in Tables Va and Table Vb, polynucleotides encoding polypeptides described in Table VI, and polynucleotide described herein as encoding polypeptides having a biological activity. Homologous sequences and fragments of SEQ ID Nos: 1-241 refer to a sequence having at least 99%, 98%, 97%, 96%, 95%, 90%, 85%, 80%, or 75% identity to these sequences. Identity may be determined using any of the computer programs and parameters described herein, including BLAST2N with the default parameters or with any modified parameters. Homologous sequences also include RNA sequences in which uridines replace the thymines in the cDNA codes of SEQ ID Nos: 1-241. The homologous sequences may be obtained using any of the procedures described herein or may result from the correction of a sequencing error as described above. Preferably the homologous sequences and fragments of SEQ

ID Nos: 1-241 include polynucleotides homologous to signal sequences and coding sequences for mature polypeptides of SEQ ID Nos: 1-31 and 33-143, polynucleotides described in Tables Va and Table Vb, polynucleotides encoding a polypeptide fragment described as a domain in Table VI, polynucleotide described herein as encoding polypeptides having a biological activity, or fragments
5 comprising at least 8, 10, 12, 15, 18, 20, 25, 28, 30, 35, 40, 50, 75, 100, 150, 200, 300, 400, 500, 1000 or 2000 consecutive nucleotides of the signal sequences and coding sequences for mature polypeptides of SEQ ID Nos: 1-31 and 33-143, polynucleotides described in Tables Va and Table Vb, polynucleotides described in Table VI, and polynucleotide described herein as encoding polypeptides having a biological activity. It will be appreciated that the cDNA codes of SEQ ID
10 Nos: 1-241 can be represented in the traditional single character format (See the inside back cover of Styer, 1995) or in any other format which records the identity of the nucleotides in a sequence.

As used herein the term “polypeptide codes of SEQ ID Nos: 242-482” encompasses the polypeptide sequences of SEQ ID Nos: 242-482, the signal peptides included in SEQ ID Nos: 242-272 and 274-384, the mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, the full-
15 length, signal peptides and mature polypeptide sequences encoded by the clone inserts of the deposited clone pool, polypeptide sequences homologous thereto, or fragments of any of the preceding sequences. Homologous polypeptide sequences refer to a polypeptide sequence having at least 99%, 98%, 97%, 96%, 95%, 90%, 85%, 80%, 75% identity to one of the polypeptide sequences of SEQ ID Nos: 242-482, the signal peptides included in SEQ ID Nos: 242-272 and 274-
20 384, the mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, the full-length, signal peptides and mature polypeptide sequences encoded by the clone inserts of the deposited clone pool. Identity may be determined using any of the computer programs and parameters described herein, including FASTA with the default parameters or with any modified parameters. The homologous sequences may be obtained using any of the procedures described herein or may result
25 from the correction of a sequencing error as described above. The polypeptide fragments comprise at least 5, 6, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150, 200, 250, 300, 350, 400, 450 or 500 consecutive amino acids of the polypeptides of SEQ ID Nos: 242-482. Preferably, the fragments include polypeptides encoded by the signal peptides included in SEQ ID Nos: 242-272 and 274-384, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, polynucleotides
30 described in Tables Va and in Table Vb, domains described in Table VI, epitopes described in Table VII, polypeptides described herein as having a biological activity, or fragments comprising at least 5, 10, 15, 20, 25, 30, 35, 40, 50, 75, 100, 150, 200, 300 or 400 consecutive amino acids of the signal peptides included in SEQ ID Nos: 242-272 and 274-384, mature polypeptides included in SEQ ID Nos: 242-272 and 274-384, the polypeptides encoded by the polynucleotides described in
35 Tables Va and in Table Vb, domains of Table VI, epitopes of Table VII or of polypeptides described herein as having a biological activity. It will be appreciated that the polypeptide codes of the SEQ ID Nos: 242-482 can be represented in the traditional single character format or three letter

format (See the inside back cover of Stryer, 1995) or in any other format which relates the identity of the polypeptides in a sequence.

It will be appreciated by those skilled in the art that the nucleic acid codes of the invention and polypeptide codes of the invention can be stored, recorded, and manipulated on any medium which can be read and accessed by a computer. As used herein, the words “recorded” and “stored” refer to a process for storing information on a computer medium. A skilled artisan can readily adopt any of the presently known methods for recording information on a computer readable medium to generate manufactures comprising one or more of the nucleic acid codes of the invention, or one or more of the polypeptide codes of the invention. Another aspect of the present invention is a computer readable medium having recorded thereon at least 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 nucleic acid codes of the invention. Another aspect of the present invention is a computer readable medium having recorded thereon at least 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 polypeptide codes of the invention.

Computer readable media include magnetically readable media, optically readable media, electronically readable media and magnetic/optical media. For example, the computer readable media may be a hard disk, a floppy disk, a magnetic tape, CD-ROM, Digital Versatile Disk (DVD), Random Access Memory (RAM), or Read Only Memory (ROM) as well as other types of other media known to those skilled in the art.

Embodiments of the present invention include systems, particularly computer systems which store and manipulate the sequence information described herein. One example of a computer system 100 is illustrated in block diagram form in Figure 2. As used herein, “a computer system” refers to the hardware components, software components, and data storage components used to analyze the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. In one embodiment, the computer system 100 is a Sun Enterprise 1000 server (Sun Microsystems, Palo Alto, CA). The computer system 100 preferably includes a processor for processing, accessing and manipulating the sequence data. The processor 105 can be any well-known type of central processing unit, such as the Pentium III from Intel Corporation, or similar processor from Sun, Motorola, Compaq or International Business Machines.

Preferably, the computer system 100 is a general purpose system that comprises the processor 105 and one or more internal data storage components 110 for storing data, and one or more data retrieving devices for retrieving the data stored on the data storage components. A skilled artisan can readily appreciate that any one of the currently available computer systems are suitable.

In one particular embodiment, the computer system 100 includes a processor 105 connected to a bus which is connected to a main memory 115 (preferably implemented as RAM) and one or more internal data storage devices 110, such as a hard drive and/or other computer readable media

having data recorded thereon. In some embodiments, the computer system 100 further includes one or more data retrieving device 118 for reading the data stored on the internal data storage devices 110.

The data retrieving device 118 may represent, for example, a floppy disk drive, a compact disk drive, a magnetic tape drive, etc. In some embodiments, the internal data storage device 110 is a removable computer readable medium such as a floppy disk, a compact disk, a magnetic tape, etc. containing control logic and/or data recorded thereon. The computer system 100 may advantageously include or be programmed by appropriate software for reading the control logic and/or the data from the data storage component once inserted in the data retrieving device.

10 The computer system 100 includes a display 120 which is used to display output to a computer user. It should also be noted that the computer system 100 can be linked to other computer systems 125a-c in a network or wide area network to provide centralized access to the computer system 100.

Software for accessing and processing the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention (such as search tools, compare tools, and modeling tools etc.) may reside in main memory 115 during execution.

In some embodiments, the computer system 100 may further comprise a sequence comparer for comparing the above-described nucleic acid codes of the invention or the polypeptide codes of the invention stored on a computer readable medium to reference nucleotide or polypeptide sequences stored on a computer readable medium. A "sequence comparer" refers to one or more programs which are implemented on the computer system 100 to compare a nucleotide or polypeptide sequence with other nucleotide or polypeptide sequences and/or compounds including but not limited to peptides, peptidomimetics, and chemicals stored within the data storage means. For example, the sequence comparer may compare the nucleotide sequences of nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention stored on a computer readable medium to reference sequences stored on a computer readable medium to identify homologies, motifs implicated in biological function, or structural motifs. The various sequence comparer programs identified elsewhere in this patent specification are particularly contemplated for use in this aspect of the invention.

30 Figure 3 is a flow diagram illustrating one embodiment of a process 200 for comparing a new nucleotide or protein sequence with a database of sequences in order to determine the homology levels between the new sequence and the sequences in the database. The database of sequences can be a private database stored within the computer system 100, or a public database such as GENBANK, PIR OR SWISSPROT that is available through the Internet.

35 The process 200 begins at a start state 201 and then moves to a state 202 wherein the new sequence to be compared is stored to a memory in a computer system 100. As discussed above, the memory could be any type of memory, including RAM or an internal storage device.

The process 200 then moves to a state 204 wherein a database of sequences is opened for analysis and comparison. The process 200 then moves to a state 206 wherein the first sequence stored in the database is read into a memory on the computer. A comparison is then performed at a state 210 to determine if the first sequence is the same as the second sequence. It is important to
5 note that this step is not limited to performing an exact comparison between the new sequence and the first sequence in the database. Well-known methods are known to those of skill in the art for comparing two nucleotide or protein sequences, even if they are not identical. For example, gaps can be introduced into one sequence in order to raise the homology level between the two tested sequences. The parameters that control whether gaps or other features are introduced into a
10 sequence during comparison are normally entered by the user of the computer system.

Once a comparison of the two sequences has been performed at the state 210, a determination is made at a decision state 210 whether the two sequences are the same. Of course, the term "same" is not limited to sequences that are absolutely identical. Sequences that are within the homology parameters entered by the user will be marked as "same" in the process 200.

15 If a determination is made that the two sequences are the same, the process 200 moves to a state 214 wherein the name of the sequence from the database is displayed to the user. This state notifies the user that the sequence with the displayed name fulfills the homology constraints that were entered. Once the name of the stored sequence is displayed to the user, the process 200 moves to a decision state 218 wherein a determination is made whether more sequences exist in the
20 database. If no more sequences exist in the database, then the process 200 terminates at an end state 220. However, if more sequences do exist in the database, then the process 200 moves to a state 224 wherein a pointer is moved to the next sequence in the database so that it can be compared to the new sequence. In this manner, the new sequence is aligned and compared with every sequence in the database.

25 It should be noted that if a determination had been made at the decision state 212 that the sequences were not homologous, then the process 200 would move immediately to the decision state 218 in order to determine if any other sequences were available in the database for comparison.

Accordingly, one aspect of the present invention is a computer system comprising a
30 processor, a data storage device having stored thereon a nucleic acid code of the invention or a polypeptide code of the invention. In some embodiments the computer system further comprises a data storage device having retrievably stored thereon reference nucleotide sequences or polypeptide sequences to be compared to the nucleic acid code of the invention or polypeptide code of the invention and a sequence comparer for conducting the comparison. For example, the sequence
35 comparer may comprise a computer program which indicates polymorphisms. In other aspects of the computer system, the system further comprises an identifier which identifies features in said sequence. The sequence comparer may indicate a homology level between the sequences compared

or identify motifs implicated in biological function and structural motifs in the nucleic acid code of the invention and polypeptide codes of the invention or it may identify structural motifs in sequences which are compared to these nucleic acid codes and polypeptide codes. In some embodiments, the data storage device may have stored thereon the sequences of at least 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 of the nucleic acid codes of the invention or polypeptide codes of the invention.

Another aspect of the present invention is a method for determining the level of homology between a nucleic acid code of the invention and a reference nucleotide sequence, comprising the steps of reading the nucleic acid code and the reference nucleotide sequence through the use of a computer program which determines homology levels and determining homology between the nucleic acid code and the reference nucleotide sequence with the computer program. The computer program may be any of a number of computer programs for determining homology levels, including those specifically enumerated herein, including BLAST2N with the default parameters or with any modified parameters. The method may be implemented using the computer systems described above. The method may also be performed by reading 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 of the above described nucleic acid codes of the invention through the use of the computer program and determining homology between the nucleic acid codes and reference nucleotide sequences.

Figure 4 is a flow diagram illustrating one embodiment of a process 250 in a computer for determining whether two sequences are homologous. The process 250 begins at a start state 252 and then moves to a state 254 wherein a first sequence to be compared is stored to a memory. The second sequence to be compared is then stored to a memory at a state 256. The process 250 then moves to a state 260 wherein the first character in the first sequence is read and then to a state 262 wherein the first character of the second sequence is read. It should be understood that if the sequence is a nucleotide sequence, then the character would normally be either A, T, C, G or U. If the sequence is a protein sequence, then it should be in the single letter amino acid code so that the first and sequence sequences can be easily compared.

A determination is then made at a decision state 264 whether the two characters are the same. If they are the same, then the process 250 moves to a state 268 wherein the next characters in the first and second sequences are read. A determination is then made whether the next characters are the same. If they are, then the process 250 continues this loop until two characters are not the same. If a determination is made that the next two characters are not the same, the process 250 moves to a decision state 274 to determine whether there are any more characters either sequence to read.

If there aren't any more characters to read, then the process 250 moves to a state 276 wherein the level of homology between the first and second sequences is displayed to the user. The level of homology is determined by calculating the proportion of characters between the sequences

that were the same out of the total number of sequences in the first sequence. Thus, if every character in a first 100 nucleotide sequence aligned with a every character in a second sequence, the homology level would be 100%.

Alternatively, the computer program may be a computer program which compares the
5 nucleotide sequences of the nucleic acid codes of the present invention, to reference nucleotide sequences in order to determine whether the nucleic acid code of the invention differs from a reference nucleic acid sequence at one or more positions. Optionally such a program records the length and identity of inserted, deleted or substituted nucleotides with respect to the sequence of either the reference polynucleotide or the nucleic acid code of the invention. In one embodiment,
10 the computer program may be a program which determines whether the nucleotide sequences of the nucleic acid codes of the invention contain one or more single nucleotide polymorphisms (SNP) with respect to a reference nucleotide sequence. These single nucleotide polymorphisms may each comprise a single base substitution, insertion, or deletion.

Another embodiment of the present invention is a method for comparing a first sequence to
15 a reference sequence wherein the first sequence is selected from the group consisting of a cDNA code of SEQID NOs. 1-297 and a polypeptide code of SEQ ID NOs. 298-594 comprising the steps of reading the first sequence and the reference sequence through use of a computer program which compares sequences and determining differences between the first sequence and the reference sequence with the computer program. In some aspects of this embodiment, said step of determining
20 differences between the first sequence and the reference sequence comprises identifying polymorphisms.

Another aspect of the present invention is a method for determining the level of homology between a polypeptide code of the invention and a reference polypeptide sequence, comprising the steps of reading the polypeptide code of the invention and the reference polypeptide sequence
25 through use of a computer program which determines homology levels and determining homology between the polypeptide code and the reference polypeptide sequence using the computer program.

Accordingly, another aspect of the present invention is a method for determining whether a nucleic acid code of the invention differs at one or more nucleotides from a reference nucleotide sequence comprising the steps of reading the nucleic acid code and the reference nucleotide
30 sequence through use of a computer program which identifies differences between nucleic acid sequences and identifying differences between the nucleic acid code and the reference nucleotide sequence with the computer program. In some embodiments, the computer program is a program which identifies single nucleotide polymorphisms The method may be implemented by the computer systems described above and the method illustrated in Figure 4. The method may also be
35 performed by reading at least 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 of the nucleic acid codes of the invention and the reference nucleotide sequences through the use of the computer

program and identifying differences between the nucleic acid codes and the reference nucleotide sequences with the computer program.

Thus, another embodiment of the present invention is a method for comparing a first sequence to a reference sequence wherein the first sequence is selected from the group consisting of the nucleic acid codes of the present invention or the polypeptide codes of the present invention comprising the steps of reading the first sequence and the reference sequence through use of a computer program which compares sequences and determining differences between the first sequence and the reference sequence with the computer program. In some aspects of this embodiment, said step of determining differences between the first sequence and the reference sequence comprises identifying polymorphisms.

Another aspect of the present invention is a method for determining the level of identity between a first sequence and a reference sequence, wherein the first sequence is selected from the group consisting of the nucleic acid codes of the present invention or the polypeptide codes of the present invention, comprising the steps of reading the first sequence and the reference sequence through the use of a computer program which determines identity levels and determining identity between the first sequence and the reference sequence with the computer program.

In other embodiments the computer based system may further comprise an identifier for identifying features within the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. An “identifier” refers to one or more programs which identifies certain features within the above-described nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. In one embodiment, the identifier may comprise a program which identifies an open reading frame in the cDNAs codes of the invention.

Another embodiment of the present invention is a method for identifying a feature in a sequence selected from the group consisting of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention comprising the steps of reading the sequence through the use of a computer program which identifies features in sequences and identifying features in the sequence with said computer program. In one aspect of this embodiment, the computer program comprises a computer program which identifies open reading frames. In a further embodiment, the computer program comprises a program that identifies linear or structural motifs in a polypeptide sequence.

Figure 5 is a flow diagram illustrating one embodiment of an identifier process 300 for detecting the presence of a feature in a sequence. The process 300 begins at a start state 302 and then moves to a state 304 wherein a first sequence that is to be checked for features is stored to a memory 115 in the computer system 100. The process 300 then moves to a state 306 wherein a database of sequence features is opened. Such a database would include a list of each feature’s attributes along with the name of the feature. For example, a feature name could be “Initiation

Codon” and the attribute would be “ATG”. Another example would be the feature name “TAATAA Box” and the feature attribute would be “TAATAA”. An example of such a database is produced by the University of Wisconsin Genetics Computer Group (www.gcg.com).

Once the database of features is opened at the state 306, the process 300 moves to a state 5 308 wherein the first feature is read from the database. A comparison of the attribute of the first feature with the first sequence is then made at a state 310. A determination is then made at a decision state 316 whether the attribute of the feature was found in the first sequence. If the attribute was found, then the process 300 moves to a state 318 wherein the name of the found feature is displayed to the user.

10 The process 300 then moves to a decision state 320 wherein a determination is made whether more features exist in the database. If no more features do exist, then the process 300 terminates at an end state 324. However, if more features do exist in the database, then the process 300 reads the next sequence feature at a state 326 and loops back to the state 310 wherein the attribute of the next feature is compared against the first sequence.

15 It should be noted, that if the feature attribute is not found in the first sequence at the decision state 316, the process 300 moves directly to the decision state 320 in order to determine if any more features exist in the database.

In another embodiment, the identifier may comprise a molecular modeling program which determines the 3-dimensional structure of the polypeptides codes of the invention. Such programs 20 may use any methods known to those skilled in the art including methods based on homology-modeling, fold recognition and *ab initio* methods as described in Sternberg *et al.*, 1999, which disclosure is hereby incorporated by reference in its entirety. In some embodiments, the molecular modeling program identifies target sequences that are most compatible with profiles representing the structural environments of the residues in known three-dimensional protein structures. (See, 25 e.g., Eisenberg *et al.*, U.S. Patent No. 5,436,850 issued July 25, 1995, which disclosure is hereby incorporated by reference in its entirety). In another technique, the known three-dimensional structures of proteins in a given family are superimposed to define the structurally conserved regions in that family. This protein modeling technique also uses the known three-dimensional structure of a homologous protein to approximate the structure of the polypeptide codes of the 30 invention. (See e.g., Srinivasan, *et al.*, U.S. Patent No. 5,557,535 issued September 17, 1996, which disclosure is hereby incorporated by reference in its entirety). Conventional homology modeling techniques have been used routinely to build models of proteases and antibodies. (Sowdhamini *et al.*, (1997)). Comparative approaches can also be used to develop three-dimensional protein models when the protein of interest has poor sequence identity to template proteins. In some cases, proteins 35 fold into similar three-dimensional structures despite having very weak sequence identities. For example, the three-dimensional structures of a number of helical cytokines fold in similar three-dimensional topology in spite of weak sequence homology.

The recent development of threading methods now enables the identification of likely folding patterns in a number of situations where the structural relatedness between target and template(s) is not detectable at the sequence level. Hybrid methods, in which fold recognition is performed using Multiple Sequence Threading (MST), structural equivalencies are deduced from the threading output using a distance geometry program DRAGON to construct a low resolution model, and a full-atom representation is constructed using a molecular modeling package such as QUANTA.

According to this 3-step approach, candidate templates are first identified by using the novel fold recognition algorithm MST, which is capable of performing simultaneous threading of multiple aligned sequences onto one or more 3-D structures. In a second step, the structural equivalencies obtained from the MST output are converted into interresidue distance restraints and fed into the distance geometry program DRAGON, together with auxiliary information obtained from secondary structure predictions. The program combines the restraints in an unbiased manner and rapidly generates a large number of low resolution model confirmations. In a third step, these low resolution model confirmations are converted into full-atom models and subjected to energy minimization using the molecular modeling package QUANTA. (See e.g., Aszódi *et al.*, (1997)).

The results of the molecular modeling analysis may then be used in rational drug design techniques to identify agents which modulate the activity of the polypeptide codes of the invention.

Accordingly, another aspect of the present invention is a method of identifying a feature within the nucleic acid codes of the invention or the polypeptide codes of the invention comprising reading the nucleic acid code(s) or the polypeptide code(s) through the use of a computer program which identifies features therein and identifying features within the nucleic acid code(s) or polypeptide code(s) with the computer program. In one embodiment, computer program comprises a computer program which identifies open reading frames. In a further embodiment, the computer program identifies linear or structural motifs in a polypeptide sequence. In another embodiment, the computer program comprises a molecular modeling program. The method may be performed by reading a single sequence or at least 2, 5, 10, 15, 20, 25, 30, 50, 75, 100, 150 or 200 of the nucleic acid codes of the invention or the polypeptide codes of the invention through the use of the computer program and identifying features within the nucleic acid codes or polypeptide codes with the computer program.

The nucleic acid codes of the invention or the polypeptide codes of the invention may be stored and manipulated in a variety of data processor programs in a variety of formats. For example, they may be stored as text in a word processing file, such as MicrosoftWORD or WORDPERFECT or as an ASCII file in a variety of database programs familiar to those of skill in the art, such as DB2, SYBASE, or ORACLE. In addition, many computer programs and databases may be used as sequence comparers, identifiers, or sources of reference nucleotide or polypeptide sequences to be compared to the nucleic acid codes of the invention or the polypeptide codes of the

invention. The following list is intended not to limit the invention but to provide guidance to programs and databases which are useful with the nucleic acid codes of the invention or the polypeptide codes of the invention. The programs and databases which may be used include, but are not limited to: MacPattern (EMBL), DiscoveryBase (Molecular Applications Group), GeneMine
5 (Molecular Applications Group), Look (Molecular Applications Group), MacLook (Molecular Applications Group), BLAST and BLAST2 (NCBI), BLASTN and BLASTX (Altschul *et al.*, 1990), FASTA (Pearson and Lipman, 1988), FASTDB (Brutlag *et al.*, 1990), Catalyst (Molecular Simulations Inc.), Catalyst/SHAPE (Molecular Simulations Inc.), Cerius2.DBAccess (Molecular Simulations Inc.), HypoGen (Molecular Simulations Inc.), Insight II, (Molecular Simulations Inc.),
10 Discover (Molecular Simulations Inc.), CHARMm (Molecular Simulations Inc.), Felix (Molecular Simulations Inc.), DelPhi, (Molecular Simulations Inc.), QuanteMM, (Molecular Simulations Inc.), Homology (Molecular Simulations Inc.), Modeler (Molecular Simulations Inc.), ISIS (Molecular Simulations Inc.), Quanta/Protein Design (Molecular Simulations Inc.), WebLab (Molecular Simulations Inc.), WebLab Diversity Explorer (Molecular Simulations Inc.), Gene Explorer
15 (Molecular Simulations Inc.), SeqFold (Molecular Simulations Inc.), the EMBL/Swissprotein database, the MDL Available Chemicals Directory database, the MDL Drug Data Report data base, the Comprehensive Medicinal Chemistry database, Derwent's World Drug Index database, the BioByteMasterFile database, the Genbank database, and the Genseqn database. Many other programs and data bases would be apparent to one of skill in the art given the present disclosure.
20 Motifs which may be detected using the above programs include sequences encoding leucine zippers, helix-turn-helix motifs, glycosylation sites, ubiquitination sites, alpha helices, and beta sheets, signal sequences encoding signal peptides which direct the secretion of the encoded proteins, sequences implicated in transcription regulation such as homeoboxes, acidic stretches, enzymatic active sites, substrate binding sites, and enzymatic cleavage sites.

25 CONCLUSION

As discussed above, the GENSET polynucleotides and polypeptides of the present invention or fragments thereof can be used for various purposes. The polynucleotides can be used to express recombinant protein for analysis, characterization or therapeutic use; as markers for tissues in which the corresponding protein is preferentially expressed (either constitutively or at a
30 particular stage of tissue differentiation or development or in disease states); as molecular weight markers on Southern gels; as chromosome markers or tags (when labeled) to identify chromosomes or to map related gene positions; as a reagent (including a labeled reagent) in assays designed to quantitatively determine levels of GENSET expression in biological samples; to compare with endogenous DNA sequences in patients to identify potential genetic disorders; as probes to
35 hybridize and thus discover novel, related DNA sequences; as a source of information to derive PCR primers for genetic fingerprinting; for selecting and making oligomers for attachment to a

"gene chip" or other support, including for examination for expression patterns; to raise anti-protein antibodies using DNA immunization techniques; and as an antigen to raise anti-DNA antibodies or elicit another immune response. Where the polynucleotide encodes a protein which binds or potentially binds to another protein (such as, for example, in a receptor-ligand interaction), the polynucleotide can also be used in interaction trap assays (such as, for example, that described in Gyuris *et al.*, (1993) to identify polynucleotides encoding the other protein with which binding occurs or to identify inhibitors of the binding interaction.

The proteins or polypeptides provided by the present invention can similarly be used in assays to determine biological activity, including in a panel of multiple proteins for high-throughput screening; to raise antibodies or to elicit another immune response; as a reagent (including the labeled reagent) in assays designed to quantitatively determine levels of the protein (or its receptor) in biological fluids; as markers for tissues in which the corresponding protein is preferentially expressed (either constitutively or at a particular stage of tissue differentiation or development or in a disease state); and, of course, to isolate correlative receptors or ligands. Where the protein binds or potentially binds to another protein (such as, for example, in a receptor-ligand interaction), the protein can be used to identify the other protein with which binding occurs or to identify inhibitors of the binding interaction. Proteins involved in these binding interactions can also be used to screen for peptide or small molecule inhibitors or agonists of the binding interaction.

Any or all of these research utilities are capable of being developed into reagent grade or kit format for commercialization as research products.

Methods for performing the uses listed above are well known to those skilled in the art. References disclosing such methods include without limitation "Molecular Cloning; A Laboratory Manual", 2d ed., Cole Spring Harbor Laboratory Press, Sambrook, J., E.F. Fritsch and T. Maniatis eds., 1989, and "Methods in Enzymology; Guide to Molecular Cloning Techniques", Academic Press, Berger and Kimmel eds., 1987, which disclosures are hereby incorporated by reference in their entireties.

Polynucleotides and proteins of the present invention can also be used as nutritional sources or supplements. Such uses include without limitation use as a protein or amino acid supplement, use as a carbon source, use as a nitrogen source and use as a source of carbohydrate. In such cases the protein or polynucleotide of the invention can be added to the feed of a particular organism or can be administered as a separate solid or liquid preparation, such as in the form of powder, pills, solutions, suspensions or capsules. In the case of microorganisms, the protein or polynucleotide of the invention can be added to the medium in or on which the microorganism is cultured.

Although this invention has been described in terms of certain preferred embodiments, other embodiments which will be apparent to those of ordinary skill in the art in view of the disclosure herein are also within the scope of this invention. Accordingly, the scope of the invention is intended to be defined only by reference to the appended claims.

EXAMPLES

Preparation of Antibody Compositions to GENSET proteins

Substantially pure protein or polypeptide is isolated from transfected or transformed cells containing an expression vector encoding a GENSET protein or a portion thereof. The concentration of protein in the final preparation is adjusted, for example, by concentration on an Amicon filter device, to the level of a few micrograms/ml. Monoclonal or polyclonal antibody to the protein can then be prepared as follows:

A. Monoclonal Antibody Production by Hybridoma Fusion

Monoclonal antibody to epitopes in the GENSET protein or a portion thereof can be prepared from murine hybridomas according to the classical method of Kohler and Milstein, (1975) or derivative methods thereof. Also see Harlow and Lane. (1988)..

Briefly, a mouse is repetitively inoculated with a few micrograms of the GENSET protein or a portion thereof over a period of a few weeks. The mouse is then sacrificed, and the antibody producing cells of the spleen isolated. The spleen cells are fused by means of polyethylene glycol with mouse myeloma cells, and the excess unfused cells destroyed by growth of the system on selective media comprising aminopterin (HAT media). The successfully fused cells are diluted and aliquots of the dilution placed in wells of a microtiter plate where growth of the culture is continued. Antibody-producing clones are identified by detection of antibody in the supernatant fluid of the wells by immunoassay procedures, such as ELISA, as originally described by Engvall, (1980), which disclosure is hereby incorporated by reference in its entirety, and derivative methods thereof. Selected positive clones can be expanded and their monoclonal antibody product harvested for use. Detailed procedures for monoclonal antibody production are described in Davis, *et al.* (1986) Section 21-2.

B. Polyclonal Antibody Production by Immunization

Polyclonal antiserum containing antibodies to heterogeneous epitopes in the GENSET protein or a portion thereof can be prepared by immunizing suitable non-human animal with the GENSET protein or a portion thereof, which can be unmodified or modified to enhance immunogenicity. A suitable non-human animal is preferably a non-human mammal is selected, usually a mouse, rat, rabbit, goat, or horse. Alternatively, a crude preparation which has been enriched for GENSET concentration can be used to generate antibodies. Such proteins, fragments or preparations are introduced into the non-human mammal in the presence of an appropriate adjuvant (e.g. aluminum hydroxide, RIBI, etc.) which is known in the art. In addition the protein, fragment or preparation can be pretreated with an agent which will increase antigenicity, such agents are known in the art and include, for example, methylated bovine serum albumin (mBSA), bovine serum albumin (BSA), Hepatitis B surface antigen, and keyhole limpet hemocyanin (KLH).

Serum from the immunized animal is collected, treated and tested according to known procedures. If the serum contains polyclonal antibodies to undesired epitopes, the polyclonal antibodies can be purified by immunoaffinity chromatography.

Effective polyclonal antibody production is affected by many factors related both to the antigen and the host species. Also, host animals vary in response to site of inoculations and dose, with both inadequate or excessive doses of antigen resulting in low titer antisera. Small doses (ng level) of antigen administered at multiple intradermal sites appears to be most reliable. Techniques for producing and processing polyclonal antisera are known in the art. An effective immunization protocol for rabbits can be found in Vaitukaitis *et al.* (1971), which disclosure is hereby incorporated by reference in its entirety.

Booster injections can be given at regular intervals, and antiserum harvested when antibody titer thereof, as determined semi-quantitatively, for example, by double immunodiffusion in agar against known concentrations of the antigen, begins to fall. See, for example, Ouchterlony *et al.*, (1973), which disclosure is hereby incorporated by reference in its entirety. Plateau concentration of antibody is usually in the range of 0.1 to 0.2 mg/ml of serum (about 12 uM). Affinity of the antisera for the antigen is determined by preparing competitive binding curves, as described, for example, by Fisher (1980), which disclosure is hereby incorporated by reference in its entirety.

Antibody preparations prepared according to either the monoclonal or the polyclonal protocol are useful in quantitative immunoassays which determine concentrations of antigen-bearing substances in biological samples; they are also used semi-quantitatively or qualitatively to identify the presence of antigen in a biological sample. The antibodies may also be used in therapeutic compositions for killing cells expressing the protein or reducing the levels of the protein in the body.

Biological assays

Assaying GENSET Secreted Proteins to Determine Whether they Bind to the Cell Surface

The secreted proteins encoded by the GENSET cDNAs, preferably the proteins of SEQ ID NOs: 242-272 and 274-384, or fragments thereof are cloned into expression vectors. The proteins are purified by size, charge, immunochromatography or other techniques familiar to those skilled in the art. Following purification, the proteins are labeled using techniques known to those skilled in the art. The labeled proteins are incubated with cells or cell lines derived from a variety of organs or tissues to allow the proteins to bind to any receptor present on the cell surface. Following the incubation, the cells are washed to remove non-specifically bound protein. The labeled proteins are detected by autoradiography. Alternatively, unlabeled proteins may be incubated with the cells and detected with antibodies having a detectable label, such as a fluorescent molecule, attached thereto.

Specificity of cell surface binding may be analyzed by conducting a competition analysis in which various amounts of unlabeled protein are incubated along with the labeled protein. The

amount of labeled protein bound to the cell surface decreases as the amount of competitive unlabeled protein increases. As a control, various amounts of an unlabeled protein unrelated to the labeled protein is included in some binding reactions. The amount of labeled protein bound to the cell surface does not decrease in binding reactions containing increasing amounts of unrelated
5 unlabeled protein, indicating that the protein encoded by the cDNA binds specifically to the cell surface.

As discussed herein, secreted proteins have been shown to have a number of important physiological effects and, consequently, represent a valuable therapeutic resource. The secreted proteins encoded by the cDNAs or fragments thereof made using any of the methods described
10 therein may be evaluated to determine their physiological activities as described below.

Assaying GENSET proteins or Fragments Thereof for Cytokine, Cell Proliferation or Cell
Differentiation Activity

Secreted proteins may act as cytokines or may affect cellular proliferation or differentiation. Many protein factors discovered to date, including all known cytokines, have exhibited activity in
15 one or more factor dependent cell proliferation assays, and hence the assays serve as a convenient confirmation of cytokine activity. The activity of a protein of the present invention is evidenced by any one of a number of routine factor dependent cell proliferation assays for cell lines including, without limitation, 32D, DA2, DA1G, T10, B9, B9/11, BaF3, MC9/G, M+ (preB M+), 2E8, RB5, DA1, 123, T1165, HT2, CTLL2, TF-1, Mo7c and CMK. The proteins encoded by the cDNAs of
20 the invention or fragments thereof may be evaluated for their ability to regulate T cell or thymocyte proliferation in assays such as those described above or in the following references, which are incorporated herein by reference: Current Protocols in Immunology, Ed. by J.E. Coligan *et al.*, Greene Publishing Associates and Wiley-Interscience; Takai *et al. J. Immunol.* 137:3494-3500, 1986. Bertagnolli *et al. J. Immunol.* 145:1706-1712, 1990. Bertagnolli *et al., Cellular Immunology*
25 133:327-341, 1991. Bertagnolli, *et al. J. Immunol.* 149:3778-3783, 1992; Bowman *et al., J. Immunol.* 152:1756-1761, 1994.

In addition, numerous assays for cytokine production and/or the proliferation of spleen cells, lymph node cells and thymocytes are known. These include the techniques disclosed in
30 Current Protocols in Immunology. J.E. Coligan *et al.* Eds., Vol 1 pp. 3.12.1-3.12.14 John Wiley and Sons, Toronto. 1994; and Schreiber, R.D. Current Protocols in Immunology., *supra* Vol 1 pp. 6.8.1-6.8.8, John Wiley and Sons, Toronto. 1994.

The proteins encoded by the cDNAs of the invention may also be assayed for the ability to regulate the proliferation and differentiation of hematopoietic or lymphopoietic cells. Many assays for such activity are familiar to those skilled in the art, including the assays in the following
35 references, which are incorporated herein by reference: Bottomly, K., Davis, L.S. and Lipsky, P.E., Measurement of Human and Murine Interleukin 2 and Interleukin 4, Current Protocols in

Immunology, J.E. Coligan *et al.* Eds. Vol 1 pp. 6.3.1-6.3.12, John Wiley and Sons, Toronto. 1991; deVries *et al.*, *J. Exp. Med.* 173:1205-1211, 1991; Moreau *et al.*, *Nature* 36:690-692, 1988; Greenberger *et al.*, *Proc. Natl. Acad. Sci. U.S.A.* 80:2931-2938, 1983; Nordan, R., Measurement of Mouse and Human Interleukin 6 Current Protocols in Immunology. J.E. Coligan *et al.* Eds. Vol 1
 5 pp. 6.6.1-6.6.5, John Wiley and Sons, Toronto. 1991; Smith *et al.*, *Proc. Natl. Acad. Sci. U.S.A.* 83:1857-1861, 1986; Bennett, F., Giannotti, J., Clark, S.C. and Turner, K.J., Measurement of Human Interleukin 11 Current Protocols in Immunology. J.E. Coligan *et al.* Eds. Vol 1 pp. 6.15.1 John Wiley and Sons, Toronto. 1991; Ciarletta, A., Giannotti, J., Clark, S.C. and Turner, K.J., Measurement of Mouse and Human Interleukin 9 Current Protocols in Immunology. J.E. Coligan *et*
 10 *al.*, Eds. Vol 1 pp. 6.13.1, John Wiley and Sons, Toronto. 1991.

The proteins encoded by the cDNAs of the invention may also be assayed for their ability to regulate T-cell responses to antigens. Many assays for such activity are familiar to those skilled in the art, including the assays described in the following references, which are incorporated herein by reference: Chapter 3 (*In vitro* Assays for Mouse Lymphocyte Function), Chapter 6 (Cytokines and
 15 Their Cellular Receptors) and Chapter 7, (Immunologic Studies in Humans) in Current Protocols in Immunology, J.E. Coligan *et al.* Eds. Greene Publishing Associates and Wiley-Interscience; Weinberger *et al.*, *Proc. Natl. Acad. Sci. USA* 77:6091-6095, 1980; Weinberger *et al.*, *Eur. J. Immunol.* 11:405-411, 1981; Takai *et al.*, *J. Immunol.* 137:3494-3500, 1986; Takai *et al.*, *J. Immunol.* 140:508-512, 1988.

20 Those proteins which exhibit cytokine, cell proliferation, or cell differentiation activity may then be formulated as pharmaceuticals and used to treat clinical conditions in which induction of cell proliferation or differentiation is beneficial. Alternatively, as described in more detail below, genes encoding these proteins or nucleic acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as
 25 desired.

Assaying GENSET proteins or Fragments Thereof for Activity as Immune System Regulators

The proteins encoded by the cDNAs of the invention may also be evaluated for their effects as immune regulators. For example, the proteins may be evaluated for their activity to influence thymocyte or splenocyte cytotoxicity. Numerous assays for such activity are familiar to those
 30 skilled in the art including the assays described in the following references, which are incorporated herein by reference: Chapter 3 (*In vitro* Assays for Mouse Lymphocyte Function 3.1-3.19) and Chapter 7 (Immunologic studies in Humans) in Current Protocols in Immunology, J.E. Coligan *et al.* Eds, Greene Publishing Associates and Wiley-Interscience; Herrmann *et al.*, *Proc. Natl. Acad. Sci. USA* 78:2488-2492, 1981; Herrmann *et al.*, *J. Immunol.* 128:1968-1974, 1982; Handa *et al.*, *J. Immunol.* 135:1564-1572, 1985; Takai *et al.*, *J. Immunol.* 137:3494-3500, 1986; Takai *et al.*, *J. Immunol.* 140:508-512, 1988; Herrmann *et al.*, *Proc. Natl. Acad. Sci. USA* 78:2488-2492, 1981;
 35

Herrmann *et al.*, *J. Immunol.* 128:1968-1974, 1982; Handa *et al.*, *J. Immunol.* 135:1564-1572, 1985; Takai *et al.*, *J. Immunol.* 137:3494-3500, 1986; Bowman *et al.*, *J. Virology* 61:1992-1998; Takai *et al.*, *J. Immunol.* 140:508-512, 1988; Bertagnolli *et al.*, *Cellular Immunology* 133:327-341, 1991; Brown *et al.*, *J. Immunol.* 153:3079-3092, 1994.

- 5 The proteins encoded by the cDNAs of the invention may also be evaluated for their effects on T-cell dependent immunoglobulin responses and isotype switching. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Maliszewski, *J. Immunol.* 144:3028-3033, 1990; Mond, J.J. and Brunswick, M Assays for B Cell Function: *In vitro* Antibody Production, Vol 10 1 pp. 3.8.1-3.8.16 in Current Protocols in Immunology. J.E. Coligan *et al* Eds., John Wiley and Sons, Toronto. 1994.

- The proteins encoded by the cDNAs of the invention may also be evaluated for their effect on immune effector cells, including their effect on Th1 cells and cytotoxic lymphocytes. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the 15 following references, which are incorporated herein by reference: Chapter 3 (*In vitro* Assays for Mouse Lymphocyte Function 3.1-3.19) and Chapter 7 (Immunologic Studies in Humans) in Current Protocols in Immunology, J.E. Coligan *et al.* Eds., Greene Publishing Associates and Wiley-Interscience; Takai *et al.*, *J. Immunol.* 137:3494-3500, 1986; Takai *et al.*; *J. Immunol.* 140:508-512, 1988; Bertagnolli *et al.*, *J. Immunol.* 149:3778-3783, 1992.

- 20 The proteins encoded by the cDNAs of the invention may also be evaluated for their effect on dendritic cell mediated activation of naive T-cells. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Guery *et al.*, *J. Immunol.* 134:536-544, 1995; Inaba *et al.*, *Journal of Experimental Medicine* 173:549-559, 1991; Macatonia *et al.*, *Journal of Immunology* 25 154:5071-5079, 1995; Porgador *et al.*, *Journal of Experimental Medicine* 182:255-260, 1995; Nair *et al.*, *Journal of Virology* 67:4062-4069, 1993; Huang *et al.*, *Science* 264:961-965, 1994; Macatonia *et al.*, *Journal of Experimental Medicine* 169:1255-1264, 1989; Bhardwaj *et al.*, *Journal of Clinical Investigation* 94:797-807, 1994; and Inaba *et al.*, *Journal of Experimental Medicine* 172:631-640, 1990.

- 30 The proteins encoded by the cDNAs of the invention may also be evaluated for their influence on the lifetime of lymphocytes. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Darzynkiewicz *et al.*, *Cytometry* 13:795-808, 1992; Gorczyca *et al.*, *Leukemia* 7:659-670, 1993; Gorczyca *et al.*, *Cancer Research* 53:1945-1951, 1993; Itoh *et al.*, *Cell* 66:233- 35 243, 1991; Zacharchuk, *Journal of Immunology* 145:4037-4045, 1990; Zamai *et al.*, *Cytometry* 14:891-897, 1993; Gorczyca *et al.*, *International Journal of Oncology* 1:639-648, 1992.

Assays for proteins that influence early steps of T-cell commitment and development include, without limitation, those described in: Antica *et al.*, Blood 84:111-117, 1994; Fine *et al.*, Cellular immunology 155:111-122, 1994; Galy *et al.*, Blood 85:2770-2778, 1995; Toki *et al.*, Proc. Nat. Acad Sci. USA 88:7548-7551, 1991.

5 Those proteins which exhibit activity as immune system regulators activity may then be formulated as pharmaceuticals and used to treat clinical conditions in which regulation of immune activity is beneficial. For example, the protein may be useful in the treatment of various immune deficiencies and disorders (including severe combined immunodeficiency (SCID)), e.g., in regulating (up or down) growth and proliferation of T and/or B lymphocytes, as well as effecting
10 the cytolytic activity of NK cells and other cell populations. These immune deficiencies may be genetic or be caused by viral (e.g., HIV) as well as bacterial or fungal infections, or may result from autoimmune disorders. More specifically, infectious diseases caused by viral, bacterial, fungal or other infection may be treatable using a protein of the present invention, including infections by HIV, hepatitis viruses, herpesviruses, mycobacteria, Leishmania spp., malaria spp. and various
15 fungal infections such as candidiasis. Of course, in this regard, a protein of the present invention may also be useful where a boost to the immune system generally may be desirable, i.e., in the treatment of cancer.

Autoimmune disorders which may be treated using a protein of the present invention include, for example, connective tissue disease, multiple sclerosis, systemic lupus erythematosus,
20 rheumatoid arthritis, autoimmune pulmonary inflammation, Guillain-Barre syndrome, autoimmune thyroiditis, insulin dependent diabetes mellitis, myasthenia gravis, graft-versus-host disease and autoimmune inflammatory eye disease. Such a protein of the present invention may also to be useful in the treatment of allergic reactions and conditions, such as asthma (particularly allergic asthma) or other respiratory problems. Other conditions, in which immune suppression is desired
25 (including, for example, organ transplantation), may also be treatable using a protein of the present invention.

Using the proteins of the invention it may also be possible to regulate immune responses, in a number of ways. Down regulation may be in the form of inhibiting or blocking an immune response already in progress or may involve preventing the induction of an immune response. The
30 functions of activated T-cells may be inhibited by suppressing T cell responses or by inducing specific tolerance in T cells, or both. Immunosuppression of T cell responses is generally an active, non-antigen-specific, process which requires continuous exposure of the T cells to the suppressive agent. Tolerance, which involves inducing non-responsiveness or anergy in T cells, is distinguishable from immunosuppression in that it is generally antigen-specific and persists after
35 exposure to the tolerizing agent has ceased. Operationally, tolerance can be demonstrated by the lack of a T cell response upon reexposure to specific antigen in the absence of the tolerizing agent.

Down regulating or preventing one or more antigen functions (including without limitation B lymphocyte antigen functions (such as, for example, B7)), e.g., preventing high level lymphokine synthesis by activated T cells, will be useful in situations of tissue, skin and organ transplantation and in graft-versus-host disease (GVHD). For example, blockage of T cell function should result in reduced tissue destruction in tissue transplantation. Typically, in tissue transplants, rejection of the transplant is initiated through its recognition as foreign by T cells, followed by an immune reaction that destroys the transplant. The administration of a molecule which inhibits or blocks interaction of a B7 lymphocyte antigen with its natural ligand(s) on immune cells (such as a soluble, monomeric form of a peptide having B7-2 activity alone or in conjunction with a monomeric form of a peptide having an activity of another B lymphocyte antigen (e.g., B7-1, B7-3) or blocking antibody), prior to transplantation can lead to the binding of the molecule to the natural ligand(s) on the immune cells without transmitting the corresponding costimulatory signal. Blocking B lymphocyte antigen function in this matter prevents cytokine synthesis by immune cells, such as T cells, and thus acts as an immunosuppressant. Moreover, the lack of costimulation may also be sufficient to anergize the T cells, thereby inducing tolerance in a subject. Induction of long-term tolerance by B lymphocyte antigen-blocking reagents may avoid the necessity of repeated administration of these blocking reagents. To achieve sufficient immunosuppression or tolerance in a subject, it may also be necessary to block the function of a combination of B lymphocyte antigens.

The efficacy of particular blocking reagents in preventing organ transplant rejection or GVHD can be assessed using animal models that are predictive of efficacy in humans. Examples of appropriate systems which can be used include allogeneic cardiac grafts in rats and xenogeneic pancreatic islet cell grafts in mice, both of which have been used to examine the immunosuppressive effects of CTLA4Ig fusion proteins *in vivo* as described in Lenschow *et al.*, Science 257:789-792 (1992) and Turka *et al.*, Proc. Natl. Acad. Sci USA, 89:11102-11105 (1992). In addition, murine models of GVHD (see Paul ed., Fundamental Immunology, Raven Press, New York, 1989, pp. 846-847) can be used to determine the effect of blocking B lymphocyte antigen function *in vivo* on the development of that disease.

Blocking antigen function may also be therapeutically useful for treating autoimmune diseases. Many autoimmune disorders are the result of inappropriate activation of T cells that are reactive against self tissue and which promote the production of cytokines and autoantibodies involved in the pathology of the diseases. Preventing the activation of autoreactive T cells may reduce or eliminate disease symptoms. Administration of reagents which block costimulation of T cells by disrupting receptor ligand interactions of B lymphocyte antigens can be used to inhibit T cell activation and prevent production of autoantibodies or T cell-derived cytokines which may be involved in the disease process. Additionally, blocking reagents may induce antigen-specific tolerance of autoreactive T cells which could lead to long-term relief from the disease. The efficacy of blocking reagents in preventing or alleviating autoimmune disorders can be determined using a

number of well-characterized animal models of human autoimmune diseases. Examples include murine experimental autoimmune encephalitis, systemic lupus erythematosus in MRL/pr/pr mice or NZB hybrid mice, murine autoimmune collagen arthritis, diabetes mellitus in OD mice and BB rats, and murine experimental myasthenia gravis (see Paul ed., Fundamental Immunology, Raven Press, New York, 1989, pp. 840-856).

Upregulation of an antigen function (preferably a B lymphocyte antigen function), as a means of up regulating immune responses, may also be useful in therapy. Upregulation of immune responses may be in the form of enhancing an existing immune response or eliciting an initial immune response. For example, enhancing an immune response through stimulating B lymphocyte antigen function may be useful in cases of viral infection. In addition, systemic viral diseases such as influenza, the common cold, and encephalitis might be alleviated by the administration of stimulatory form of B lymphocyte antigens systemically.

Alternatively, anti-viral immune responses may be enhanced in an infected patient by removing T cells from the patient, costimulating the T cells *in vitro* with viral antigen-pulsed APCs either expressing a peptide of the present invention or together with a stimulatory form of a soluble peptide of the present invention and reintroducing the *in vitro* activated T cells into the patient. The infected cells would now be capable of delivering a costimulatory signal to T cells *in vivo*, thereby activating the T cells.

In another application, up regulation or enhancement of antigen function (preferably B lymphocyte antigen function) may be useful in the induction of tumor immunity. Tumor cells (e.g., sarcoma, melanoma, lymphoma, leukemia, neuroblastoma, carcinoma) transfected with a nucleic acid encoding at least one peptide of the present invention can be administered to a subject to overcome tumor-specific tolerance in the subject. If desired, the tumor cell can be transfected to express a combination of peptides. For example, tumor cells obtained from a patient can be transfected *ex vivo* with an expression vector directing the expression of a peptide having B7-2-like activity alone, or in conjunction with a peptide having B7-1-like activity and/or B7-3-like activity. The transfected tumor cells are returned to the patient to result in expression of the peptides on the surface of the transfected cell. Alternatively, gene therapy techniques can be used to target a tumor cell for transfection *in vivo*.

The presence of the peptide of the present invention having the activity of a B lymphocyte antigen(s) on the surface of the tumor cell provides the necessary costimulation signal to T cells to induce a T cell mediated immune response against the transfected tumor cells. In addition, tumor cells which lack MHC class I or MHC class II molecules, or which fail to reexpress sufficient amounts of MHC class I or MHC class II molecules, can be transfected with nucleic acids encoding all or a fragment of (e.g., a cytoplasmic-domain truncated fragment) of an MHC class I α chain protein and β_2 microglobulin protein or an MHC class II α chain protein and an MHC class II β chain protein to thereby express MHC class I or MHC class II proteins on the cell surface.

Expression of the appropriate class II or class II MHC in conjunction with a peptide having the activity of a B lymphocyte antigen (e.g., B7-1, B7-2, B7-3) induces a T cell mediated immune response against the transfected tumor cell. Optionally, a gene encoding an antisense construct which blocks expression of an MHC class II associated protein, such as the invariant chain, can also be cotransfected with a DNA encoding a peptide having the activity of a B lymphocyte antigen to promote presentation of tumor associated antigens and induce tumor specific immunity. Thus, the induction of a T cell mediated immune response in a human subject may be sufficient to overcome tumor-specific tolerance in the subject. Alternatively, as described in more detail below, genes encoding these proteins or nucleic acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as desired.

Assaying GENSET proteins or Fragments Thereof for Hematopoiesis Regulating Activity

The proteins encoded by the cDNAs of the invention or fragments thereof may also be evaluated for their hematopoiesis regulating activity. For example, the effect of the proteins on embryonic stem cell differentiation may be evaluated. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Johansson *et al.* *Cellular Biology* 15:141-151, 1995; Keller *et al.*, *Molecular and Cellular Biology* 13:473-486, 1993; McClanahan *et al.*, *Blood* 81:2903-2915, 1993.

The proteins encoded by the cDNAs of the invention or fragments thereof may also be evaluated for their influence on the lifetime of stem cells and stem cell differentiation. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Freshney, M.G. Methylcellulose Colony Forming Assays, in Culture of Hematopoietic Cells. R.I. Freshney, *et al.* Eds. pp. 265-268, Wiley-Liss, Inc., New York, NY. 1994; Hirayama *et al.*, *Proc. Natl. Acad. Sci. USA* 89:5907-5911, 1992; McNiece, I.K. and Briddell, R.A. Primitive Hematopoietic Colony Forming Cells with High Proliferative Potential, in Culture of Hematopoietic Cells. R.I. Freshney, *et al.* eds. Vol pp. 23-39, Wiley-Liss, Inc., New York, NY. 1994; Neben *et al.*, *Experimental Hematology* 22:353-359, 1994; Ploemacher, R.E. Cobblestone Area Forming Cell Assay, In Culture of Hematopoietic Cells. R.I. Freshney, *et al.* Eds. pp. 1-21, Wiley-Liss, Inc., New York, NY. 1994; Spooncer, E., Dexter, M. and Allen, T. Long Term Bone Marrow Cultures in the Presence of Stromal Cells, in Culture of Hematopoietic Cells. R.I. Freshney, *et al.* Eds. pp. 163-179, Wiley-Liss, Inc., New York, NY. 1994; and Sutherland, H.J. Long Term Culture Initiating Cell Assay, in Culture of Hematopoietic Cells. R.I. Freshney, *et al.* Eds. pp. 139-162, Wiley-Liss, Inc., New York, NY. 1994.

Those proteins which exhibit hematopoiesis regulatory activity may then be formulated as pharmaceuticals and used to treat clinical conditions in which regulation of hematopoiesis is

beneficial. For example, a protein of the present invention may be useful in regulation of hematopoiesis and, consequently, in the treatment of myeloid or lymphoid cell deficiencies. Even marginal biological activity in support of colony forming cells or of factor-dependent cell lines indicates involvement in regulating hematopoiesis, e.g. in supporting the growth and proliferation of erythroid progenitor cells alone or in combination with other cytokines, thereby indicating utility, for example, in treating various anemias or for use in conjunction with irradiation/chemotherapy to stimulate the production of erythroid precursors and/or erythroid cells; in supporting the growth and proliferation of myeloid cells such as granulocytes and monocytes/macrophages (i.e., traditional CSF activity) useful, for example, in conjunction with chemotherapy to prevent or treat consequent myelo-suppression; in supporting the growth and proliferation of megakaryocytes and consequently of platelets thereby allowing prevention or treatment of various platelet disorders such as thrombocytopenia, and generally for use in place of or complimentary to platelet transfusions; and/or in supporting the growth and proliferation of hematopoietic stem cells which are capable of maturing to any and all of the above-mentioned hematopoietic cells and therefore find therapeutic utility in various stem cell disorders (such as those usually treated with transplantation, including, without limitation, aplastic anemia and paroxysmal nocturnal hemoglobinuria), as well as in repopulating the stem cell compartment post irradiation/chemotherapy, either in-vivo or ex-vivo (i.e., in conjunction with bone marrow transplantation or with peripheral progenitor cell transplantation (homologous or heterologous)) as normal cells or genetically manipulated for gene therapy. Alternatively, as described in more detail below, genes encoding these proteins or nucleic acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as desired.

Assaying GENSET proteins or Fragments Thereof for Regulation of Tissue Growth

The proteins encoded by the cDNAs of the invention or fragments thereof may also be evaluated for their effect on tissue growth. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in International Patent Publication No. WO95/16035, International Patent Publication No. WO95/05846 and International Patent Publication No. WO91/07491, which are incorporated herein by reference.

Assays for wound healing activity include, without limitation, those described in: Winter, Epidermal Wound Healing, pps. 71-112 (Maibach, H1 and Rovee, DT, eds.), Year Book Medical Publishers, Inc., Chicago, as modified by Eaglstein and Mertz, J. Invest. Dermatol 71:382-84 (1978) which are incorporated herein by reference.

Those proteins which are involved in the regulation of tissue growth may then be formulated as pharmaceuticals and used to treat clinical conditions in which regulation of tissue growth is beneficial. For example, a protein of the present invention also may have utility in compositions used for bone, cartilage, tendon, ligament and/or nerve tissue growth or regeneration,

as well as for wound healing and tissue repair and replacement, and in the treatment of burns, incisions and ulcers.

A protein of the present invention, which induces cartilage and/or bone growth in circumstances where bone is not normally formed, has application in the healing of bone fractures and cartilage damage or defects in humans and other animals. Such a preparation employing a protein of the invention may have prophylactic use in closed as well as open fracture reduction and also in the improved fixation of artificial joints. De novo bone formation induced by an osteogenic agent contributes to the repair of congenital, trauma induced, or oncologic resection induced craniofacial defects, and also is useful in cosmetic plastic surgery.

10 A protein of this invention may also be used in the treatment of periodontal disease, and in other tooth repair processes. Such agents may provide an environment to attract bone-forming cells, stimulate growth of bone-forming cells or induce differentiation of progenitors of bone-forming cells. A protein of the invention may also be useful in the treatment of osteoporosis or osteoarthritis, such as through stimulation of bone and/or cartilage repair or by blocking inflammation or processes of tissue destruction (collagenase activity, osteoclast activity, etc.) mediated by inflammatory processes.

Another category of tissue regeneration activity that may be attributable to the protein of the present invention is tendon/ligament formation. A protein of the present invention, which induces tendon/ligament-like tissue or other tissue formation in circumstances where such tissue is not normally formed, has application in the healing of tendon or ligament tears, deformities and other tendon or ligament defects in humans and other animals. Such a preparation employing a tendon/ligament-like tissue inducing protein may have prophylactic use in preventing damage to tendon or ligament tissue, as well as use in the improved fixation of tendon or ligament to bone or other tissues, and in repairing defects to tendon or ligament tissue. De novo tendon/ligament-like tissue formation induced by a composition of the present invention contributes to the repair of congenital, trauma induced, or other tendon or ligament defects of other origin, and is also useful in cosmetic plastic surgery for attachment or repair of tendons or ligaments. The compositions of the present invention may provide an environment to attract tendon- or ligament-forming cells, stimulate growth of tendon- or ligament-forming cells, induce differentiation of progenitors of tendon- or ligament-forming cells, or induce growth of tendon/ligament cells or progenitors *ex vivo* for return *in vivo* to effect tissue repair. The compositions of the invention may also be useful in the treatment of tendinitis, carpal tunnel syndrome and other tendon or ligament defects. The compositions may also include an appropriate matrix and/or sequestering agent as a carrier as is well known in the art.

35 The protein of the present invention may also be useful for proliferation of neural cells and for regeneration of nerve and brain tissue, i.e., for the treatment of central and peripheral nervous system diseases and neuropathies, as well as mechanical and traumatic disorders, which involve

degeneration, death or trauma to neural cells or nerve tissue. More specifically, a protein may be used in the treatment of diseases of the peripheral nervous system, such as peripheral nerve injuries, peripheral neuropathy and localized neuropathies, and central nervous system diseases, such as Alzheimer's, Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, and Shy-
5 Drager syndrome. Further conditions which may be treated in accordance with the present invention include mechanical and traumatic disorders, such as spinal cord disorders, head trauma and cerebrovascular diseases such as stroke. Peripheral neuropathies resulting from chemotherapy or other medical therapies may also be treatable using a protein of the invention.

Proteins of the invention may also be useful to promote better or faster closure of non-
10 healing wounds, including without limitation pressure ulcers, ulcers associated with vascular insufficiency, surgical and traumatic wounds, and the like.

It is expected that a protein of the present invention may also exhibit activity for generation or regeneration of other tissues, such as organs (including, for example, pancreas, liver, intestine, kidney, skin, endothelium) muscle (smooth, skeletal or cardiac) and vascular (including vascular
15 endothelium) tissue, or for promoting the growth of cells comprising such tissues. Part of the desired effects may be by inhibition or modulation of fibrotic scarring to allow normal tissue to generate. A protein of the invention may also exhibit angiogenic activity.

A protein of the present invention may also be useful for gut protection or regeneration and treatment of lung or liver fibrosis, reperfusion injury in various tissues, and conditions resulting
20 from systemic cytokine damage.

A protein of the present invention may also be useful for promoting or inhibiting differentiation of tissues described above from precursor tissues or cells; or for inhibiting the growth of tissues described above.

Alternatively, as described in more detail below, genes encoding these proteins or nucleic
25 acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as desired.

Assaying GENSET proteins or Fragments Thereof for Regulation of Reproductive Hormones or Cell Movement

The proteins encoded by the cDNAs of the invention or fragments thereof may also be
30 evaluated for their ability to regulate reproductive hormones, such as follicle stimulating hormone. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Vale *et al.*, *Endocrinology* 91:562-572, 1972; Ling *et al.*, *Nature* 321:779-782, 1986; Vale *et al.*, *Nature* 321:776-779, 1986; Mason *et al.*, *Nature* 318:659-663, 1985; Forage *et al.*, *Proc. Natl. Acad. Sci.*
35 *USA* 83:3091-3095, 1986. Chapter 6.12 (Measurement of Alpha and Beta Chemokines) Current Protocols in Immunology, J.E. Coligan *et al.* Eds. Greene Publishing Associates and Wiley-

Interscience ; Taub *et al. J. Clin. Invest.* 95:1370-1376, 1995; Lind *et al. APMIS* 103:140-146, 1995; Muller *et al. Eur. J. Immunol.* 25:1744-1748; Gruber *et al. J. of Immunol.* 152:5860-5867, 1994; Johnston *et al. J. of Immunol.* 153:1762-1768, 1994.

Those proteins which exhibit activity as reproductive hormones or regulators of cell movement may then be formulated as pharmaceuticals and used to treat clinical conditions in which regulation of reproductive hormones or cell movement are beneficial. For example, a protein of the present invention may also exhibit activin- or inhibin-related activities. Inhibins are characterized by their ability to inhibit the release of follicle stimulating hormone (FSH), while activins are characterized by their ability to stimulate the release of follicle stimulating hormone (FSH). Thus, a protein of the present invention, alone or in heterodimers with a member of the inhibin α family, may be useful as a contraceptive based on the ability of inhibins to decrease fertility in female mammals and decrease spermatogenesis in male mammals. Administration of sufficient amounts of other inhibins can induce infertility in these mammals. Alternatively, the protein of the invention, as a homodimer or as a heterodimer with other protein subunits of the inhibin-B group, may be useful as a fertility inducing therapeutic, based upon the ability of activin molecules in stimulating FSH release from cells of the anterior pituitary. See, for example, United States Patent 4,798,885, the disclosure of which is incorporated herein by reference. A protein of the invention may also be useful for advancement of the onset of fertility in sexually immature mammals, so as to increase the lifetime reproductive performance of domestic animals such as cows, sheep and pigs.

Alternatively, as described in more detail below, genes encoding these proteins or nucleic acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as desired.

Assaying GENSET proteins or Fragments Thereof for Chemotactic/Chemokinetic Activity

The proteins encoded by the cDNAs of the invention or fragments thereof may also be evaluated for chemotactic/chemokinetic activity. For example, a protein of the present invention may have chemotactic or chemokinetic activity (e.g., act as a chemokine) for mammalian cells, including, for example, monocytes, fibroblasts, neutrophils, T-cells, mast cells, eosinophils, epithelial and/or endothelial cells. Chemotactic and chemokinetic proteins can be used to mobilize or attract a desired cell population to a desired site of action. Chemotactic or chemokinetic proteins provide particular advantages in treatment of wounds and other trauma to tissues, as well as in treatment of localized infections. For example, attraction of lymphocytes, monocytes or neutrophils to tumors or sites of infection may result in improved immune responses against the tumor or infecting agent.

A protein or peptide has chemotactic activity for a particular cell population if it can stimulate, directly or indirectly, the directed orientation or movement of such cell population. Preferably, the protein or peptide has the ability to directly stimulate directed movement of cells.

Whether a particular protein has chemotactic activity for a population of cells can be readily determined by employing such protein or peptide in any known assay for cell chemotaxis.

The activity of a protein of the invention may, among other means, be measured by the following methods:

- 5 Assays for chemotactic activity (which will identify proteins that induce or prevent chemotaxis) consist of assays that measure the ability of a protein to induce the migration of cells across a membrane as well as the ability of a protein to induce the adhesion of one cell population to another cell population. Suitable assays for movement and adhesion include, without limitation, those described in: Current Protocols in Immunology, Ed by J.E. Coligan, A.M. Kruisbeek, D.H. Margulies, E.M. Shevach, W. Strober, Pub. Greene Publishing Associates and Wiley-Interscience (Chapter 6.12, Measurement of alpha and beta Chemokines 6.12.1-6.12.28; Taub *et al.* J. Clin. Invest. 95:1370-1376, 1995; Lind *et al.* APMIS 103:140-146, 1995; Mueller *et al.* Eur. J. Immunol. 25:1744-1748; Gruber *et al.* J. of Immunol. 152:5860-5867, 1994; Johnston *et al.* J. of Immunol, 153:1762-1768, 1994.

15 Assaying GENSET proteins or Fragments Thereof for Regulation of Blood Clotting

- The proteins encoded by the cDNAs of the invention or fragments thereof may also be evaluated for their effects on blood clotting. Numerous assays for such activity are familiar to those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Linet *et al.*, *J. Clin. Pharmacol.* 26:131-140, 1986; Burdick *et al.*, *Thrombosis Res.* 45:413-419, 1987; Humphrey *et al.*, *Fibrinolysis* 5:71-79 (1991); Schaub, *Prostaglandins* 35:467-474, 1988.

- Those proteins which are involved in the regulation of blood clotting may then be formulated as pharmaceuticals and used to treat clinical conditions in which regulation of blood clotting is beneficial. For example, a protein of the invention may also exhibit hemostatic or thrombolytic activity. As a result, such a protein is expected to be useful in treatment of various coagulations disorders (including hereditary disorders, such as hemophilias) or to enhance coagulation and other hemostatic events in treating wounds resulting from trauma, surgery or other causes. A protein of the invention may also be useful for dissolving or inhibiting formation of thromboses and for treatment and prevention of conditions resulting therefrom (such as, for example, infarction of cardiac and central nervous system vessels (e.g., stroke)). Alternatively, as described in more detail below, genes encoding these proteins or nucleic acids regulating the expression of these proteins may be introduced into appropriate host cells to increase or decrease the expression of the proteins as desired.

Assaying GENSET proteins or Fragments Thereof for Involvement in Receptor/Ligand Interactions

- 35 The proteins encoded by the cDNAs or a fragment thereof may also be evaluated for their involvement in receptor/ligand interactions. Numerous assays for such involvement are familiar to

those skilled in the art, including the assays disclosed in the following references, which are incorporated herein by reference: Chapter 7.28 (Measurement of Cellular Adhesion under Static Conditions 7.28.1-7.28.22) in Current Protocols in Immunology, J.E. Coligan *et al.* Eds. Greene Publishing Associates and Wiley-Interscience; Takai *et al.*, *Proc. Natl. Acad. Sci. USA* 84:6864-6868, 1987; Bierer *et al.*, *J. Exp. Med.* 168:1145-1156, 1988; Rosenstein *et al.*, *J. Exp. Med.* 169:149-160, 1989; Stoltenborg *et al.*, *J. Immunol. Methods* 175:59-68, 1994; Stitt *et al.*, *Cell* 80:661-670, 1995; Gyuris *et al.*, *Cell* 75:791-803, 1993.

For example, the proteins of the present invention may also demonstrate activity as receptors, receptor ligands or inhibitors or agonists of receptor/ligand interactions. Examples of such receptors and ligands include, without limitation, cytokine receptors and their ligands, receptor kinases and their ligands, receptor phosphatases and their ligands, receptors involved in cell-cell interactions and their ligands (including without limitation, cellular adhesion molecules (such as selectins, integrins and their ligands) and receptor/ligand pairs involved in antigen presentation, antigen recognition and development of cellular and humoral immune responses). Receptors and ligands are also useful for screening of potential peptide or small molecule inhibitors of the relevant receptor/ligand interaction. A protein of the present invention (including, without limitation, fragments of receptors and ligands) may themselves be useful as inhibitors of receptor/ligand interactions.

Assaying GENSET proteins or Fragments Thereof for Anti-Inflammatory Activity

The proteins encoded by the cDNAs or a fragment thereof may also be evaluated for anti-inflammatory activity. The anti-inflammatory activity may be achieved by providing a stimulus to cells involved in the inflammatory response, by inhibiting or promoting cell-cell interactions (such as, for example, cell adhesion), by inhibiting or promoting chemotaxis of cells involved in the inflammatory process, inhibiting or promoting cell extravasation, or by stimulating or suppressing production of other factors which more directly inhibit or promote an inflammatory response. Proteins exhibiting such activities can be used to treat inflammatory conditions including chronic or acute conditions), including without limitation inflammation associated with infection (such as septic shock, sepsis or systemic inflammatory response syndrome (SIRS)), ischemia-reperfusion injury, endotoxin lethality, arthritis, complement-mediated hyperacute rejection, nephritis, cytokine or chemokine-induced lung injury, inflammatory bowel disease, Crohn's disease or resulting from over production of cytokines such as TNF or IL-1. Proteins of the invention may also be useful to treat anaphylaxis and hypersensitivity to an antigenic substance or material.

Assaying GENSET proteins or Fragments Thereof for Tumor Inhibition Activity

The proteins encoded by the cDNAs of the invention or a fragment thereof may also be evaluated for tumor inhibition activity. In addition to the activities described above for immunological treatment or prevention of tumors, a protein of the invention may exhibit other anti-

tumor activities. A protein may inhibit tumor growth directly or indirectly (such as, for example, via ADCC). A protein may exhibit its tumor inhibitory activity by acting on tumor tissue or tumor precursor tissue, by inhibiting formation of tissues necessary to support tumor growth (such as, for example, by inhibiting angiogenesis), by causing production of other factors, agents or cell types
 5 which inhibit tumor growth, or by suppressing, eliminating or inhibiting factors, agents or cell types which promote tumor growth.

A protein of the invention may also exhibit one or more of the following additional activities or effects: inhibiting the growth, infection or function of, or killing, infectious agents, including, without limitation, bacteria, viruses, fungi and other parasites; effecting (suppressing or
 10 enhancing) bodily characteristics, including, without limitation, height, weight, hair color, eye color, skin, fat to lean ratio or other tissue pigmentation, or organ or body part size or shape (such as, for example, breast augmentation or diminution, change in bone form or shape); effecting biorhythms or circadian cycles or rhythms; effecting the fertility of male or female subjects; effecting the metabolism, catabolism, anabolism, processing, utilization, storage or elimination of
 15 dietary fat, lipid, protein, carbohydrate, vitamins, minerals, cofactors or other nutritional factors or component(s); effecting behavioral characteristics, including, without limitation, appetite, libido, stress, cognition (including cognitive disorders), depression (including depressive disorders) and violent behaviors; providing analgesic effects or other pain reducing effects; promoting differentiation and growth of embryonic stem cells in lineages other than hematopoietic lineages;
 20 hormonal or endocrine activity; in the case of enzymes, correcting deficiencies of the enzyme and treating deficiency-related diseases; treatment of hyperproliferative disorders (such as, for example, psoriasis); immunoglobulin-like activity (such as, for example, the ability to bind antigens or complement); and the ability to act as an antigen in a vaccine composition to raise an immune response against such protein or another material or entity which is cross-reactive with such protein.

Throughout this application, various publications, patents and published patent applications
5 are cited. The disclosures of these publications, patents and published patent specification
referenced in this application are hereby incorporated by reference into the present disclosure to
more fully describe the state of the art to which this invention pertains.

Table VI

Seq Id No	Designation of domain	Database	Positions of domains
242	Cell attachment sequence	PROSITE	141-143
242	Peptidase family M20/M25/M40	PFAM	107-451
244	Mitochondrial energy transfer proteins signature	PROSITE	26-35
244	Mitochondrial energy transfer proteins signature	PROSITE	199-208
244	Mitochondrial carrier proteins	PFAM	5-84;87-175;178-272
244	Mitochondrial energy transfer proteins.	BLOCKSPLUS	12-36
244	Mitochondrial energy transfer proteins.	BLOCKSPLUS	13-36
244	Mitochondrial energy transfer proteins.	BLOCKSPLUS	131-144
245	Leucine zipper pattern	PROSITE	371-392
249	Leucine zipper pattern	PROSITE	20-41
251	Mitochondrial energy transfer proteins signature	PROSITE	26-35
251	Mitochondrial carrier proteins	PFAM	5-72
251	Mitochondrial energy transfer proteins.	BLOCKSPLUS	12-36
251	Mitochondrial energy transfer proteins.	BLOCKSPLUS	13-36
254	Pancreatic ribonuclease family signature	PROSITE	63-69
254	Pancreatic ribonucleases	PFAM	26-143
254	PANCREATIC RIBONUCLEASE FAMILY SIGNATURE	BLOCKSPLUS	49-69
254	Pancreatic ribonuclease family proteins.	BLOCKSPLUS	115-140
254	PANCREATIC RIBONUCLEASE FAMILY SIGNATURE	BLOCKSPLUS	92-110
254	PANCREATIC RIBONUCLEASE FAMILY SIGNATURE	BLOCKSPLUS	114-133
254	Pancreatic ribonuclease family proteins.	BLOCKSPLUS	30-40
254	PANCREATIC RIBONUCLEASE FAMILY SIGNATURE	BLOCKSPLUS	114-137
254	PANCREATIC RIBONUCLEASE FAMILY SIGNATURE	BLOCKSPLUS	69-86
255	L-lactate dehydrogenase active site	PROSITE	239-245
255	lactate/malate dehydrogenase	PFAM	71-380
255	L-lactate dehydrogenase proteins.	BLOCKSPLUS	186-224
255	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	96-121
255	L-lactate dehydrogenase proteins.	BLOCKSPLUS	71-102
255	L-lactate dehydrogenase proteins.	BLOCKSPLUS	238-256
255	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	183-203
255	L-lactate dehydrogenase proteins.	BLOCKSPLUS	288-323

255	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	207-224
255	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	71-92
255	L-lactate dehydrogenase proteins.	BLOCKSPLUS	138-167
256	lactate/malate dehydrogenase	PFAM	71-124
256	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	96-121
256	L-lactate dehydrogenase proteins.	BLOCKSPLUS	71-102
256	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	71-92
256	L-lactate dehydrogenase proteins.	BLOCKSPLUS	71-100
256	L-LACTATE DEHYDROGENASE SIGNATURE	BLOCKSPLUS	71-84
257	Leucine zipper pattern	PROSITE	155-176
259	HORMA domain	PFAM	22-230
261	Leucine zipper pattern	PROSITE	142-163
261	Leucine zipper pattern	PROSITE	170-191
263	Leucine zipper pattern	PROSITE	15-36
264	Ubiquitin family	PFAM	1-82
264	Ubiquitin domain proteins.	BLOCKSPLUS	17-62
264	Ubiquitin domain proteins.	BLOCKSPLUS	21-68
264	Ubiquitin domain proteins.	BLOCKSPLUS	26-68
264	Ubiquitin domain proteins.	BLOCKSPLUS	17-68
266	u-PAR/Ly-6 domain	PFAM	60-119
266	Squash family of serine protease inhibit	PFAM	32-47
267	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	185-202
271	LBP / BPI / CETP family signature	PROSITE	28-60
271	Pyrokinins signature	PROSITE	324-328
271	LBP / BPI / CETP family	PFAM	10-479
271	LBP / BPI / CETP family proteins.	BLOCKSPLUS	72-118
271	LBP / BPI / CETP family proteins.	BLOCKSPLUS	209-253
271	LBP / BPI / CETP family proteins.	BLOCKSPLUS	28-58
271	LBP / BPI / CETP family proteins.	BLOCKSPLUS	275-309
271	LBP / BPI / CETP family proteins.	BLOCKSPLUS	76-113
272	Zinc finger, C3HC4 type (RING finger), signature	PROSITE	102-111
272	Zinc finger, C3HC4 type (RING finger)	PFAM	87-129
272	Zinc finger, C3HC4 type (RING finger), proteins.	BLOCKSPLUS	102-111
273	Zinc finger, C3HC4 type (RING finger), signature	PROSITE	30-39
273	Zinc finger, C3HC4 type (RING finger)	PFAM	15-57
273	Zinc finger, C3HC4 type (RING finger), proteins.	BLOCKSPLUS	30-39
274	RNA 3'-terminal phosphate cyclase signature	PROSITE	157-167
274	RNA 3'-terminal phosphate cyclase	PFAM	1-368

274	RNA 3'-terminal phosphate cyclase proteins.	BLOCKSPLUS	12-44
274	RNA 3'-terminal phosphate cyclase proteins.	BLOCKSPLUS	157-168
275	Ribosomal L27 protein	PFAM	31-86
277	Cell attachment sequence	PROSITE	292-294
277	DHHC zinc finger domain	PFAM	140-204
279	Endogenous opioids neuropeptides precursors signature	PROSITE	26-65
279	Vertebrate endogenous opioids neurope	PFAM	3-257
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	100-126
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	209-237
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	43-66
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	18-38
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	24-36
279	Endogenous opioids neuropeptides precursors proteins.	BLOCKSPLUS	105-125
280	Leucine zipper pattern	PROSITE	136-157
280	Leucine zipper pattern	PROSITE	272-293
283	Immunoglobulins and major histocompatibility complex proteins signature	PROSITE	380-386
283	Immunoglobulin domain	PFAM	205-285;318-384
283	Immunoglobulins and major histocompatibility complex proteins.	BLOCKSPLUS	319-336
284	Fucosyl transferase	PFAM	70-406
285	FAD/NAD-binding Cytochrome reductase	PFAM	27-149
285	Oxidoreductase FAD/NAD-binding domain	PFAM	176-290
285	Eukaryotic molybdopterin oxidoreductases proteins.	BLOCKSPLUS	58-86
285	CYTOCHROME B5 REDUCTASE SIGNATURE	BLOCKSPLUS	75-86
285	CYTOCHROME B5 REDUCTASE SIGNATURE	BLOCKSPLUS	274-283
285	CYTOCHROME B5 REDUCTASE SIGNATURE	BLOCKSPLUS	141-156
285	Eukaryotic molybdopterin oxidoreductases proteins.	BLOCKSPLUS	274-286
285	Eukaryotic molybdopterin oxidoreductases proteins.	BLOCKSPLUS	60-85
285	CYTOCHROME B5 REDUCTASE SIGNATURE	BLOCKSPLUS	181-198
285	FLAVOPROTEIN PYRIDINE NUCLEOTIDE CYTOCHROME REDUCTASE SIGNATURE	BLOCKSPLUS	181-197

286	Immunoglobulins and major histocompatibility complex proteins signature	PROSITE	380-386
286	Immunoglobulin domain	PFAM	205-285;318-384
286	Immunoglobulins and major histocompatibility complex proteins.	BLOCKSPLUS	319-336
287	Leucine zipper pattern	PROSITE	126-147
288	Leucine zipper pattern	PROSITE	20-41
291	Tissue inhibitors of metalloproteinases signature	PROSITE	24-36
291	Tissue inhibitor of metalloproteinases	PFAM	22-199
291	Tissue inhibitors of metalloproteinases proteins.	BLOCKSPLUS	21-46
291	Tissue inhibitors of metalloproteinases proteins.	BLOCKSPLUS	106-148
291	Tissue inhibitors of metalloproteinases proteins.	BLOCKSPLUS	81-95
291	Tissue inhibitors of metalloproteinases proteins.	BLOCKSPLUS	61-72
294	Domain of unknown function DUF59	PFAM	31-135
296	Immunoglobulin domain	PFAM	141-197
297	TonB-dependent receptor proteins signature 1	PROSITE	1-42
298	Fibroblast growth factor	PFAM	48-129
299	BolA-like protein	PFAM	39-114
299	PROTEIN BOLA TRANSCRIPTION REGULATION AC.	BLOCKSPLUS	68-98
301	Cell attachment sequence	PROSITE	172-174
303	Ribosomal L27 protein	PFAM	31-115
304	Leucine rich repeat C-terminal domain	PFAM	173-222
304	Leucine Rich Repeat	PFAM	92-115;116-139;140-163;164-185
309	Leucine rich repeat C-terminal domain	PFAM	173-222
309	Leucine Rich Repeat	PFAM	92-115;116-139;140-163;164-185
311	NOL1/NOP2/sun family	PFAM	201-276;353-378
311	NOL1/NOP2/sun family proteins.	BLOCKSPLUS	230-245
311	NOL1/NOP2/sun family proteins.	BLOCKSPLUS	231-245
312	NOL1/NOP2/sun family	PFAM	201-276
312	NOL1/NOP2/sun family proteins.	BLOCKSPLUS	230-245
312	NOL1/NOP2/sun family proteins.	BLOCKSPLUS	231-245
314	Leucine zipper pattern	PROSITE	8-29
315	Leucine zipper pattern	PROSITE	8-29
341	Immunoglobulin domain	PFAM	45-112
349	CDP-alcohol phosphatidyltransferases signature	PROSITE	54-76
349	Cytochrome b/b6 Qo site signature	PROSITE	97-102
354	SAM domain (Sterile alpha motif)	PFAM	82-147
361	Ribosomal Proteins L2	PFAM	96-124
368	DAD family	PFAM	1-78
370	Ribosomal protein L34	PFAM	51-92

385	Kelch motif	PFAM	20-66;68-114;116-162;164-209;211-265;270-316
386	SPRY domain	PFAM	85-205
388	PHD-finger.	BLOCKSPLUS	329-339
389	Eukaryotic thiol (cysteine) proteases histidine active site	PROSITE	268-278
389	Heat shock hsp70 proteins family signature 3	PROSITE	332-346
389	Hsp70 protein	PFAM	3-509
390	Eukaryotic-type carbonic anhydrase	PFAM	20-59
391	PMP-22/EMP/MP20/Claudin family	PFAM	4-162
392	Sec1 family.	BLOCKSPLUS	89-107
393	PMP-22/EMP/MP20/Claudin family	PFAM	4-182
394	Myc-type, 'helix-loop-helix' dimerization domain signature	PROSITE	13-28
395	Glutathione S-transferases.	PFAM	47-122;260-309
396	Transmembrane 4 family signature	PROSITE	112-134
396	Transmembrane 4 family	PFAM	66-273
396	Transmembrane 4 family proteins.	BLOCKSPLUS	108-146
396	TRANSMEMBRANE FOUR FAMILY SIGNATURE	BLOCKSPLUS	129-151
396	TRANSMEMBRANE FOUR FAMILY SIGNATURE	BLOCKSPLUS	108-127
396	TRANSMEMBRANE FOUR FAMILY SIGNATURE	BLOCKSPLUS	247-274
396	TRANSMEMBRANE FOUR FAMILY SIGNATURE	BLOCKSPLUS	129-150
396	TRANSMEMBRANE FOUR FAMILY SIGNATURE	BLOCKSPLUS	128-154
397	ATP/GTP-binding site motif A (P-loop)	PROSITE	6-13
397	ADP-ribosylation factor family	PFAM	2-172
398	Isochorismatase family	PFAM	17-147
399	PAP2 superfamily	PFAM	19-175
400	Zinc carboxypeptidases, zinc-binding region 2 signature	PROSITE	117-127
401	Zinc finger, C2H2 type, domain	PROSITE	36-57
401	Zinc finger, C2H2 type, domain	PROSITE	73-93
401	Zinc finger, C2H2 type, domain	PROSITE	114-134
401	Zinc finger, C2H2 type, domain	PROSITE	145-165
401	Zinc finger, C2H2 type	PFAM	34-57;71-93;112-134;143-165
401	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	145-162
401	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	114-131
401	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	73-90
402	Zinc finger, C2H2 type, domain	PROSITE	113-133

402	Zinc finger, C2H2 type, domain	PROSITE	144-164
402	Regulator of chromosome condensation (RCC1) signature 2	PROSITE	65-75
402	Zinc finger, C2H2 type	PFAM	111-133;142-164
402	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	144-161
402	Zinc finger, C2H2 type, domain proteins.	BLOCKSPLUS	113-130
403	Glutathione S-transferases.	PFAM	47-122;260-309
405	PMP-22/EMP/MP20/Claudin family	PFAM	4-182
406	WD domain, G-beta repeat	PFAM	267-304;333-370
408	Rhomboid family	PFAM	186-323
410	Ank repeat	PFAM	47-79
410	REPEAT PROTEIN ANK NUCLEAR ANKYR.	BLOCKSPLUS	78-89
410	Ank repeat proteins.	BLOCKSPLUS	48-56
412	Serine proteases, subtilase family, aspartic acid proteins.	BLOCKSPLUS	165-178
414	Sir2 family	PFAM	84-268
416	Kelch motif	PFAM	20-66;68-114;116-162;164-209;211-265;270-316
418	Zinc-binding dehydrogenases	PFAM	16-313
426	Leucine zipper pattern	PROSITE	144-165
447	Cytochrome c family heme-binding site signature	PROSITE	19-24
447	Immunoglobulins and major histocompatibility complex proteins signature	PROSITE	17-23
453	eIF-6 family	PFAM	3-103
454	Cell attachment sequence	PROSITE	226-228
456	Leucine zipper pattern	PROSITE	211-232
457	Leucine zipper pattern	PROSITE	236-257
466	Zinc finger, C3HC4 type (RING finger), signature	PROSITE	56-65
466	SPRY domain	PFAM	375-500
466	Zinc finger, C3HC4 type (RING finger)	PFAM	41-81
466	B-box zinc finger.	PFAM	110-153
466	Domain in SPla and the RYanodine Receptor.	BLOCKSPLUS	359-381
466	Domain in SPla and the RYanodine Receptor.	BLOCKSPLUS	443-457
466	Domain in SPla and the RYanodine Receptor.	BLOCKSPLUS	359-380
466	Zinc finger, C3HC4 type (RING finger), proteins.	BLOCKSPLUS	56-65
479	UBX domain	PFAM	329-408
481	TBC domain	PFAM	65-171
481	Probable rabGAP domain proteins.	BLOCKSPLUS	153-159
482	TBC domain	PFAM	65-177

482	Probable rabGAP domain proteins.	BLOCKSPLUS	153-159

WHAT IS CLAIMED IS:

1. An isolated polynucleotide, said polynucleotide comprising a nucleic acid sequence encoding:
 - 5 i) a polypeptide comprising an amino acid sequence having at least about 80% identity to any one of the sequences shown as SEQ ID NOs:242-482 or any one of the sequences of polypeptides encoded by the clone inserts of the deposited clone pool; or
 - 10 ii) a biologically active fragment of said polypeptide.
2. The polynucleotide of claim 1, wherein said polypeptide comprises any one of the sequences shown as SEQ ID NOs:242-482 or any one of the sequences of the polypeptides encoded by the clone inserts of the deposited clone pool.
- 15 3. The polynucleotide of claim 1, wherein said polypeptide comprises a signal peptide.
4. The polynucleotide of claim 1, wherein said polypeptide is a mature protein.
5. The polynucleotide of claim 1, wherein said nucleic acid sequence has at least about
20 80% identity over at least about 100 contiguous nucleotides to any one of the sequences shown as SEQ ID NOs:1-241 or any one of the sequences of the clone inserts of the deposited clone pool.
6. The polynucleotide of claim 1, wherein said polynucleotide hybridizes under stringent conditions to a polynucleotide comprising any one of the sequences shown as SEQ ID
25 NOs:1-241 or any one of the sequences of the clone inserts of the deposited clone pool.
7. The polynucleotide of claim 5, wherein said nucleic acid sequence comprises any one of the sequences shown as SEQ ID NOs:1-241 or any one the sequences of the clone inserts of the deposited clone pool.
30
8. The polynucleotide of claim 1, wherein said polynucleotide is operably linked to a promoter.
9. An expression vector comprising the polynucleotide of claim 8.
35
10. A host cell recombinant for the polynucleotide of claim 1.

11. A non-human transgenic animal comprising the host cell of claim 10.
12. A method of making a GENSET polypeptide, said method comprising
- 5 a) providing a population of host cells comprising the polynucleotide of claim 8; and
- b) culturing said population of host cells under conditions conducive to the production of said polypeptide within said host cells.
13. The method of claim 12, further comprising purifying said polypeptide from said
- 10 population of host cells.
14. A method of making a GENSET polypeptide, said method comprising
- a) providing a population of cells comprising the polynucleotide of claim 8;
- 15 b) culturing said population of cells under conditions conducive to the production of said polypeptide within said cells; and
- c) purifying said polypeptide from said population of cells.
15. An isolated polynucleotide, said polynucleotide comprising a nucleic acid sequence
- 20 having at least about 80% identity over at least about 100 contiguous nucleotides to any one of the sequences shown as SEQ ID NOs:1-241 or any one of the sequences of the clone inserts of the deposited clone pool.
16. The polynucleotide of claim 15, wherein said polynucleotide hybridizes under
- 25 stringent conditions to a polynucleotide comprising any one of the sequences shown as SEQ ID NOs:1-241 or any one of the sequences of the clone inserts of the deposited clone pool.
17. The polynucleotide of claim 15, wherein said polynucleotide comprises any one of the sequences shown as SEQ ID NOs:1-241 or any one of the sequences of the clone inserts of the
- 30 deposited clone pool.
18. A biologically active polypeptide encoded by the polynucleotide of claim 15.
19. An isolated polypeptide or biologically active fragment thereof, said polypeptide
- 35 comprising an amino acid sequence having at least about 80% sequence identity to any one of the sequences shown as SEQ ID NOs:242-482 or any one of the sequences of polypeptides encoded by the clone inserts of the deposited clone pool.

20. The polypeptide of claim 19, wherein said polypeptide is selectively recognized by an antibody raised against an antigenic polypeptide, or an antigenic fragment thereof, said antigenic polypeptide comprising any one of the sequences shown as SEQ ID NOs:242-482 or any one of the sequences of polypeptides encoded by the clone inserts of the deposited clone pool.

21. The polypeptide of claim 19, wherein said polypeptide comprises any one of the sequences shown as SEQ ID NOs:242-482 or any one of the sequences of polypeptides encoded by the clone inserts of the deposited clone pool.

10

22. The polypeptide of claim 19, wherein said polypeptide comprises a signal peptide.

23. The polypeptide of claim 19, wherein said polypeptide is a mature protein.

24. An antibody that specifically binds to the polypeptide of claim 19.

25. A method of determining whether a GENSET gene is expressed within a mammal, said method comprising the steps of:

- a) providing a biological sample from said mammal
- b) contacting said biological sample with either of:
 - i) a polynucleotide that hybridizes under stringent conditions to the polynucleotide of claim 1; or
 - ii) a polypeptide that specifically binds to the polypeptide of claim 19; and
- c) detecting the presence or absence of hybridization between said polynucleotide and an RNA species within said sample, or the presence or absence of binding of said polypeptide to a protein within said sample;

wherein a detection of said hybridization or of said binding indicates that said GENSET gene is expressed within said mammal.

26. The method of claim 25, wherein said polynucleotide is a primer, and wherein said hybridization is detected by detecting the presence of an amplification product comprising the sequence of said primer.

27. The method of claim 25, wherein said polypeptide is an antibody.

35

28. A method of determining whether a mammal has an elevated or reduced level of GENSET gene expression, said method comprising the steps of :

- a) providing a biological sample from said mammal; and
- b) comparing the amount of the polypeptide of claim 19, or of an RNA species encoding said polypeptide, within said biological sample with a level detected in or expected from a control sample;

5 wherein an increased amount of said polypeptide or said RNA species within said biological sample compared to said level detected in or expected from said control sample indicates that said mammal has an elevated level of said GENSET gene expression, and wherein a decreased amount of said polypeptide or said RNA species within said biological sample compared to said level detected in or expected from said control sample indicates that said mammal has a reduced level of
10 said GENSET gene expression.

29. A method of identifying a candidate modulator of a GENSET polypeptide, said method comprising :

- a) contacting the polypeptide of claim 18 with a test compound; and
- 15 b) determining whether said compound specifically binds to said polypeptide;

 wherein a detection that said compound specifically binds to said polypeptide indicates that said compound is a candidate modulator of said GENSET polypeptide.
